Other types of baked pastries included *pechen'ya* (cookies), *prianik* (a type of honey-cake), *sooshka* (ring-shaped pretzels, small *kalatch* dipped into boiling water before baking); *smetannyya kalatchiki* (baked pies of unleavened dough based on sour cream), and *kulich* (Easter cake with raisins or other dry fruits).

**Oils and fats.** Unlike that of European Russia, Siberian cookery involved many fried dishes. The reason for this is simple: Chaldons had a lot of vegetable oil. The most common oils were hemp-seed and linseed oils; rarer were sunflower and poppy-seed oils. The most expensive oil was pine-nut oil, produced only in forest areas. Since Siberians had many cows, they produced large quantities of butter, which was even exported to Europe. The Chaldony, however, preferred drawn butter for frying foods. The use of fish oil was adopted from local fishermen tribes. It was very rarely used in European Russia, but in the north of Siberia it served as a substitute for vegetable oils. For example, in northern Siberia, pies were fried in tenc oil.

**Meat.** At the beginning of the twentieth century, meat was one of the main features of the Siberian menu. It was always on the table, excluding, of course, fasting days preceding the big Christian holidays, as well as Wednesday and Friday of every week.

The most important meats were beef, lamb, chicken, and goose. Meat-and-cabbage soup, called *shchi*, was usually cooked on a daily basis. Borscht, the red-beet meat soup, was popular among settlers from southern Russia. Due to the convenience of Russian ovens, boiling or stewing was the most common way of cooking meat.

According to the old custom only three-year-old bulls, “that had enough time to put on weight,” were slaughtered for meat. *Kolbasa* (sausages) were traditionally made of beef; only at the end of the nineteenth

century did Chaldon cooks learn recipes for pork *kolbasa* from newly arrived European immigrants. Horse meat was also used for sausages and was cooked in a variety of ways in the areas where Russian Siberians were in close contact with horse-breeding aboriginals. The Chaldony applied the same logic to reindeer venison in the areas of reindeer-raising tribes and to *maral* (Siberian deer) venison in the Altay Mountains of southern Siberia.

One of the most popular traditional foods in Siberia was aspic or meat jelly, called *kholodets*. It came from the legs and ears of cows and pigs that are boiled for a long time over a low heat. The meat was then cut off the bones, chopped into very fine pieces, and covered with its broth. Usually onion, garlic, and black pepper were added, as well as carrots and other root vegetables. Especially delicate was the *kholodets* made of duck, goose, or chicken feet, which required the most laborious preparation. *Kholodets* was usually served with very hot Russian mustard or horseradish sauce, often as a cold meal accompanied by vodka.

*Kotlety*, an oval-shaped rissole made from a mixture of minced beef and pork (with additions of onion, garlic, and white bread soaked in milk), was adopted from German settlers, as were *rybny* and *kurinny kotlety*, made from minced fish or chicken.

***Pel'meni.*** *Pel'meni* was a very distinctive Siberian stuffed pasta dish traditionally cooked during winter. In form, *pel'meni* was a thin round (about 2–3 inches in diameter) of soft pasta dough folded over a minced meat filling to make a semicircle, with the two arms (the corners) twisted around and stuck together. One could find hundreds of *pel'meni* filling recipes involving chicken, game birds, elk, fish, reindeer, mushrooms, and many vegetarian variations; some restaurants even used meat from a brown bear as a local delicacy. However, the filling was made traditionally of two (beef and pork) or three (with the addition of lamb) types of meat, along with onion, salt, and ground black pepper.

In some villages, Chaldony made thousands of *pel'meni* during the first cold winter weeks, freezing them in the *seni* (unheated hallway) and storing them in sacks for consumption as fast-cooking food throughout the winter. *Pel'meni* were not cooked over steam, as many similar central Asian dishes were; rather they were boiled in water. In the past, *pel'meni* was the food normally given to travellers, especially to the *yamschik* (winter coachmen) who conveyed goods and passengers by *sani* (sleds) over huge distances of Siberia. The name *pel'meni* originates from the Komi language: *pel'*, meaning 'ear', and *nian'*, meaning 'bread'. In turn, the origin of Komi's *pel'nian* recipe can be traced to thirteenth-century China. When the Russian colonization of Siberia began at the end of the sixteenth century, Perm', the land of Komi, was used as the base for expansion. Not only did all Russian expeditions to Siberia go through Perm', where Russians learned about *pel'meni*, but also about 30 percent of the

colonists were recruited from the Komi people. As a result, *pel'meni* spread throughout the huge colony and became a Siberian national dish.

***Fish.*** Fish is a plentiful and favorite food of native Siberians. It is used for *ouba* (fish soup), pies, frying, and for pickling. Siberians love baked stuffed fish (usually pike); some scholars consider that it was adopted from Jewish cuisine, but differences in the recipe show that it is an indigenous local dish. *Eekra* (caviar) in Siberian cookery is not just a delicacy but also an everyday food. Siberians also make flat round caviar cakes—usually these cakes are just pure fried caviar, sometimes with the addition of chopped onion, black pepper, and a little flour. Fresh sterlet, sturgeon, salmon, or pike caviar is served slightly salted and mixed with fresh chopped onions.

From Siberian aborigines the Chaldony adopted such simple but extremely tasty food as fish *stroganina* or *chush*—thin chips cut from a large boneless piece of fresh frozen fish. *Chush* is a kind of simple but delicious accompaniment for vodka, usually eaten straight or with salt and black pepper, sometimes with chopped onion and vinegar.

***Milk and egg dishes.*** Households of Siberian old-timers usually had many milk cows. *Tvorog* (cottage cheese) and *smetana* (sour cream) were mixed together to make a popular breakfast dish (a kind of thick yogurt) that was often eaten with honey or berry jams. In the areas near Turkic tribes, dried cottage cheese cakes were popular, and in Altay, cottage cheese cakes were smoked. *Tvorog* is the base for the dough of the popular Siberian *syrniki* (thick flat cottage cheese pancakes); it is made by combining *tvorog*, flour, milk, and eggs. *Paskha* (literally Easter, or in this case, traditional Russian Easter cake) is also based on cottage cheese mixed with eggs, raisins, honey, and candied fruits. Sour cream is used as a base for sauces and almost always as a soup dressing for *shchi*, borsch, mushroom soup, *okroshka*, and other soups, as well as a base for sweet cake creams.

***Mushrooms and other wild plants.*** Mushrooms are an important source of proteins and are an essential raw material in Siberian cuisine: they are used in Siberian cooking much more often than in Europe. Many a Siberian family can collect up to 700–1,100 pounds of various wild mushrooms over a typical season (June to the end of September) just for the family's use. Agaric mushrooms are used for pickling with such ingredients as brine, dill, horseradish, and garlic, and, sometimes, oriental spices like black pepper, bay leaf, and cloves are added. Only saffron milk cap, chanterelle, and sometimes *Armillaria* (honey mushrooms) are fried on their own or stewed with potatoes. *Armillaria* can also be dried together with all spongy mushrooms: cep, brown cap boletus, orange-cap boletus, mossiness mushroom, *Boletus luteus*. In addition to drying for later use for winter mushroom soup or frying, spongy mushrooms are fried or stewed with pota-

*Pel'meni* are generally served with a variety of other foods, including special homemade bread, fish roe, sour cream, and of course, vodka. PHOTO BY ILYA VIKTOROVICH LOYSHA COURTESY OF STOLICHNAYA RUSSIAN VODKA.

toes, added to kashas, baked with eggs, and used in various mushroom soups.

**Festive food.** Patron saints' days, the so-called *gulaschi den'* (idle day) when nobody works, were planned well in advance. People made vodka and beer days ahead of time. Lots of guests from the neighborhood were invited into homes, and groups of people went from place to place visiting different houses. Every house had to prepare ample food, as in every house people were eating, drinking, singing, and dancing. Such holidays were only meant for married couples; young people were not entitled to take part in the feast.

For such feasts people always made pancakes, honey-cakes, cookies, and various pastries. Meat- and fish-jelly and fish pie were some standards among a great number of other dishes. Before the guests approached the table, they would offer their good wishes to the hosts: "Bread on the table and salt on the table. Let it always be this way for you." After the meal and the merriment, parting guests would say: "Our Lord, save the hosts; give them good health, concord and ransom."

A Chaldon funeral repast consisted of a minimum of twelve dishes. The first items on the menu were the *kut'ya* (boiled-rice funereal dish), then *bliny*, boiled eggs sliced

in half, and *okroshka* (cold soup) with meat. Chicken and meat soups, mushrooms, corned beef, aspic, meat and chicken, boiled meatballs, and kashas followed. The last dish was fruit compote or berry kissel along with small pies or a big sweet pie. Strong drinks were not served.

For the funeral repast usually all people who knew the deceased were invited. Then ninth day, fortieth day, and one year funeral repasts followed. For the ninth day repast, just relatives and those who were helping at the funeral and funeral party were in attendance; for the forty days meal, all who came for the ninth day and those who dug the grave attended. All who came to the funeral were invited to the one year repast.

The table at a wedding celebration was especially rich: the party was three days long and cost a lot of money. A tale from the Tomsk province tells of a wedding party where everything was ready and in place, but the bride's previous boyfriend stole her away. As much money and effort had been spent in preparation for the party; the empty-handed bridegroom decided to marry another girl, saying: "Since everything is ready why should I throw out so much food?"

*Maslenitsa* (Shrovetide) was the last week before Lent. Traditional foods for this time included *bliny*, fish,

and caviar. The best food, including lots of meat, was prepared for *Paskha* (Easter). Traditionally painted eggs, *kulich*, and *Paskha* (the Easter cake) were also served. Christmas merrymaking took place over the course of three to four days. Pork gammons, chickens, and turkeys were cooked, as well as lots of pies with various fillings.

### General Changes and Foreign Foods

In spite of political changes and the pressure of permanent shortages during the eighty years of Soviet rule, Siberians have preserved a large portion of their traditional culinary identity. A new, entrepreneurial approach is underway to market the foods of the region both for local consumption and for export. In the beginning of the twentieth century, European, especially French, influence was evident only in the cuisine of the upper classes and in restaurant cooking. It has now extended to the food customs of ordinary people, and some other influences have appeared as well. In cities, central Asian foods such as *shurpa* (meat and vegetable soup), *bishbarmak* (noodle and meat soup), *shabslyk* (small pieces of marinated meat grilled on sticks), *manty* (pasta stuffed with meat and onion, then steamed), and *plov* (rice pilaf and meat) are now quite popular. Many markets sell Korean prepared salads, and the basic Korean hot carrot salad is so popular that many Siberian families now own a special grater to cut carrots to make their own version of this salad at home. Young fern shoots that are salted, dried, or fresh became popular in the Altay region after locals started stocking it in the 1980s for orders from Japan. Perhaps of all the foreign influences now affecting the cuisine of Siberia, the foods of Japan and Korea are becoming the most widely accepted.

### Siberia's Aboriginal Peoples

Historically all of the territory in Siberia can be divided into two large cultural (and economic) parts: the South—a region of ancient stockbreeding and agriculture, and the North—territories that have been populated by hunting, fishing, and reindeer-raising tribes. An overview of the cooking of the two major Siberian aboriginal ethnic groups, the Yakout (Saha) in eastern Siberia and the Khant of Finnic origin in western Siberia, may provide some idea of aboriginal Siberian cooking.

#### Yakout (Saha) People

Yakouts are of Turkish origin and number about 380,000 people. They follow the Christian Orthodox religion, but with some remnants of shamanism. Their country, Saha (Yakoutia), has one of the most severe climates in Siberia; it lies in the far northeastern part of Siberia and occupies an area of about 1.1 million square miles (which is about twelve times the size of Great Britain).

Between the tenth and fifteenth centuries C.E., the Mongols forced Yakout tribes out of their homeland in the steppes of south Siberia. There is clear linguistic proof of the Yakouts' southern origin: their language has

such words as *khoy* (ram) and *khakhbay* (tiger), even though in their country both do not exist. The environment of Yakoutia is forest, steppes on the sandy frozen meadows, and thermokarst lakes (arctic lakes formed when water holds heat that thaws the permafrost below). People live mainly in the areas of river meadows.

Yakouts are surrounded by various fishing, hunting, and reindeer-raising tribes. While the Yakout people have lived in this inclement climate over the centuries, they have not changed their traditional lifestyle of southern horse- and cattle-breeding nomads. Yakout horse, an extremely hearty breed, is the base of the traditional Yakout economy and their traditional cuisine. Yakout food is very rich in fats, including many milk, cream, and sour-milk products, and meat. Yakout people do not eat mushrooms.

**Milk products.** The traditional Yakout breakfast is *kuerchab*—a kind of sweet Western-style yogurt that is made of fresh cream and red whortleberries (very sour fruit) whipped into a homogeneous paste. *Kuerchab* is also frozen to make little round cakes, which in some cases include sugar. Another Yakout breakfast dish is a cake of dried cottage cheese.

**Meat.** The main meat for Yakouts is horseflesh, or more specifically, the meat of one-year-old colts. The horses graze all year on open pasture, in winter digging the food from under the snow, but the ones that are raised for meat are given extra food.

Thus for a year, a Yakout family of six people eats one and a half carcasses of horseflesh, a half carcass of beef, and three to four pigs. Reindeer venison is not eaten as it is considered unfit for consumption. Soviet collective farms bred reindeer, sheep, and even camels; but these meats were never popular.

The best *khan* (blood and milk pudding or sausage) is made from cow's milk and horseflesh (beef can be used but it is not as good). For spices, wild onion, garlic, and black pepper are added. These sausages are kept fresh-frozen, and boiled just before consumption.

**Soups and bread.** The most characteristic and popular is the beef intestines and flour soup. A fish soup is made with crucian (a kind of carp). From the beginning of Russian colonization in the seventeenth century, wheat and rye were introduced to Yakoutia and have been grown successfully ever since. Traditional Yakout bread is an unleavened flat cake. Modern Yakouts eat also "Russian" yeast-raised bread and make thick pancakes rather than the wide variety of pies known to the other Siberians. As a dainty treat, traditional bread is cut into squares and mixed with cream made of milk and butter, then it is frozen.

**Vegetables.** In modern times, Yakouts plant vegetables in greenhouses, but traditionally the Yakout people collected and preserved wild vegetables. Every spring they

collected a lot of wild green onions that grew along the river Lena; these fresh onions were added to all dishes and were kept salted for year-round use. Wild garlic and some other plants were also collected. In springtime children eat the soft cones of larch trees, as these cones have a pleasant tart taste and contain a high quantity of vitamin C.

**Beverages.** The Yakouts drink *Chay* (tea) with cream or milk all day long. *Mors*, a fruit drink made of red whortleberries, is consumed instead of water. There are also many sour-milk drinks, like milk whey and herbs (tansy, thyme, wormwood), which is drunk on hot summer days as a cooling and tonic drink. For an alcoholic drink, fermented mare's milk is preferred: it provides the basis of such drinks as *koumiss* (which includes herbs such as wormwood) and *araghy*.

**Festive food.** *Salamat*, a ritual dish, is a type of rich buttery flour porridge. *Salamat* is served at weddings, housewarmings, funerals, and at many other important events. Since Yakouts are Russian Orthodox, funerals and funeral repasts are performed according to Russian Orthodox traditions. However, there is one important difference: all the personal possessions of the deceased have to be burned, only the most intimate belongings are put on top of the coffin, and what can not be burned is disposed of in the garbage.

### Khant People

Until the 1930s, the Khant people were called Ostiak. Their dietary laws are very much influenced by their religion and taboos, and mystery and legend govern many of the Khant people's actions, including eating habits. For example, people of the beaver clan cannot eat beaver, and people of the elk clan cannot eat elk. Elk meat cannot be cut with a knife or even salted.

The bear is a relative to all Khants and is considered the guardian of world order, arbitrator, and the judge. Especially sacred is the front part of the bear: no woman is allowed to touch it. Dogs must not have any access to a bear's bones, and bear bones are not cut or broken. The Khant people believe that if they follow all of these rules, then a consumed bear will regain his flesh and walk again in the forest. Boiling crucian in the same cauldron as other fish is also prohibited, because crucian is fish for the dead who live in the underworld. All things white are holy and belong to their god, and therefore cannot be eaten, such as swans, ermine, and albino deer.

The cooking custom involving the burbot (a freshwater fish of the cod family) is also illustrative of the Khant people's reliance on tradition and mystery. Once burbot is caught, a Khant fisherman takes the fish's liver out through its mouth. If he succeeds in getting out all the liver, the rest of the flesh is eaten as well. But if the liver is cut and only a part of it is removed, the fish has to be released to the two sides of the world: the lower side (North) and upper side (South). The extracted liver is

grilled on wooden sticks at the side of a bonfire. But the wood of the bonfire must be of the kind that is pleasing to the god. Willow wood is used for burbot liver cooking.

The whole cuisine of the Khant people is based on the products of fishing and hunting. Fish are so important that even the bread of the Khants is made with the addition of fish powder, and the main source of fat in their cooking is fish oil. Khants drink *chai* (tea) and eat dry wild berries for sweets.

## CHRISTENING SPOONS

Wealthy Romans customarily presented a silver spoon to a newborn child. To be “born with a silver spoon in its mouth” meant that the child had many advantages from birth. When the Roman Empire adopted Christianity in 312 C.E., Romans continued to give silver spoons to newborns. To indicate that the child had been baptized, the Chi-Rho, or XP, the Greek symbol for Christ, was engraved on the bowl of the spoon. The Corinium spoon was found in Roman ruins in England, near what is now Cirencester, called Corinium during the Roman occupation of Britain. Sterling silver replicas of the christening spoon were sold in the 1970s by Leonard Jones Ltd. of Cirencester.

**SILVERWARE.** “Silverware” often refers generically to any flatware used for eating by most people in the Western world, and some parts of Asia and Africa—knives, forks, and spoons—whether it is made of silver, stainless steel, or a silver-plated base metal. Flatware, especially that used by most people when they eat informally, is usually made of stainless steel, not silver. “Silverware” also refers to dishes used for serving food and some decorative objects such as candlesticks.

In its narrowest sense, “silverware,” which includes eating utensils, serving dishes, and decorative items, is made either of sterling silver—925 parts silver to 75 parts another metal, perhaps copper—or has layers of silver plated over another metal, often nickel silver. The more layers, the better the quality, and buyers are cautioned that flatware will be more durable and worth having if it is at least triple plate. Some manufacturers put extra silver on pieces at the point of most wear, for example, on the back of the bowl of a spoon, where it rests on the table.

Of the three pieces of cutlery used by most often by Westerners for eating, the knife was the first utensil. Because early humans were hunters and scavengers and ate meat when they could get it, knives—made of flint or obsidian—were necessary both for cutting meat away from the bone of a kill and for cutting it into manageable pieces for carrying it back to the campsite and for eating. Gradually, as metallurgy developed, knives were made of bronze, iron, and, finally, steel.

From the earliest times until well into the Middle Ages, knives were used for hunting and personal protection, and men always carried them. Because no utensils were provided with meals at the inns and taverns at that time, travelers used their own knives, which they also kept on the table in case they were attacked. Later, inns began to supply knives with the food they served.

Early spoons, used for eating liquids, were made of wood. Shells with attached wooden handles were also used fashioned as spoons. Metal spoons, when they began to be used, were made from the same metal used to make knives of the era. Forks were used in Roman kitchens, with smaller versions being used to carve meat at the side of the table. It is said that a Byzantine princess introduced table forks into Venice in the eleventh century, and their use as eating utensils spread across Italy. Eating with forks did not become fashionable, however, until the seventeenth century. The fact that forks had only two tines at first may account for the delay in adopting them as eating utensils because they were awkward to use. Thomas Coryate, an English traveler, is credited with introducing forks to England in 1608 after a visit to Italy. He wrote that forks were usually made of steel or iron, but that the nobility ate with silver forks. As the use of forks became popular, people began to carry their own forks in special cases when they dined at friends' homes.

Since the Romans, silver has been used to make utensils, but only royalty or the very wealthy could afford it until the end of the nineteenth century. Indeed, the ability to own and control precious metals has always been the prerogative of nobility and the wealthy merchant classes. During the Ottoman Empire, for example, only the Sultans ate from gold dishes, while the women of the harem had silver dishes for dining.

In the eighteenth century, silver eating utensils and serving pieces were popular in Europe and America for those who could afford them. Gorham Manufacturing Company began making table silver in the United States in 1831. Each piece was hand-forged, and two men could produce two dozen pieces a day. In eighteenth-century American society, silverware was identified with women of the moneyed classes. At that time, women could not legally own land or other property, so the scope of their lives was limited to home and family. For this reason, silverware was significant as a woman's contribution to the financial part of a marriage, and it was often purchased for her one piece at a time and kept in what was called a “hope chest,” along with other household goods such as linens and quilts. Because it was bought with a woman's taste in mind, most silverware was designed for women. Silver flatware, along with other household goods, has traditionally been monogrammed with the bride's initials.

During the latter part of the nineteenth and early part of the twentieth centuries, wealthy families had servants who prepared and served elaborate dinners that required the use of many different pieces of silverware. There was a great amount of flatware and hollowware made from silver, and some of those servants were responsible for keeping all of it polished. It was a task that kept them busy. Complete sets of silver flatware came

with specialized versions of the standard utensils: luncheon knives and forks, smaller than those used for dinner; place spoons (later called “soup spoons” in the United States and “dessert spoons” in Europe, but still listed as place spoons by manufacturers), which are larger than teaspoons; and salad forks and dessert forks, often the same fork used interchangeably. Specialty items of flatware included: iced drink spoons and fish cocktail forks, both long-handled and still available in flatware sets; butter spreaders, short knives that fit on bread plates in individual place settings (also still available); chocolate spoons for hot chocolate; ramekin forks (smaller than salad forks, to fit into small dishes—called ramekins—used to bake individual servings of food); tea forks and knives, about the size of luncheon silverware; sifting spoons with pierced bowls, to be used in sifting sugar over food; fruit knives; and demitasse, or coffee, spoons.

There was even special flatware made for children: pap spoons, which were small spoons with slightly elongated handles for feeding infants; small versions of forks and spoons for children old enough to feed themselves; and pushers, each piece with a plough-like blade attached at a right angle to the handle, used to push food onto a fork or spoon.

People in European countries also enjoyed silver flatware, but used different pieces specialized to accommodate Continental eating habits, for example, marrow spoons. These are long, narrow scoops, suitable for digging flavorful marrow out of meat bones. Special fish knives and forks are also used extensively. The fish knife has a broad flat blade, which makes lifting the flesh from the bones easy, and the fork tines are usually not as sharp as those of other forks. The flatware made to serve fish is similar, but larger. Fish sets are still used in European homes and restaurants, especially in Germany, Scandinavia, and Britain.

Serving pieces used in Europe, the United States, and Canada include tomato servers (or slices), which are flat, circular, slotted pieces; tongs, ranging from large ones for serving salad or asparagus to very small ones for sugar cubes; cheese scoops, used to serve from large chunks of cheeses; dressing or stuffing spoons (called “hash spoons” in Ireland and Scotland), large, long-handled spoons suitable for digging stuffing from the insides of turkeys; ladles; and strainer spoons (like sifter spoons), used secularly to strain seeds from fruit punch bowls and ecclesiastically to strain impurities from the communion wine. Potato forks, wide, with six tines, were made in Liverpool, London, and Dublin. There were spoons for serving candy, nuts, and ice cream. Specialty forks were made to serve sardines, macaroni, and poached eggs. There were grape shears, cracker scoops, butter picks, nut picks, and lobster picks. Pie and cake servers and serrated cake knives are still being made. (A cake knife can be engraved with the names of a bride and groom and given to them for a wedding gift.) Berry serving spoons have broad, deep bowls, and lemon forks are short, with three tines, wide

apart. The most common serving pieces are tablespoons, some with holes for straining vegetables served in their cooking liquid, and meat forks.

Flatware has also been made of silver combined with various other materials such as gold, porcelain, wood, or enameled metals other than silver. Inspiration from other cultures influenced styles of silver produced in the United States. Textile designs and other forms of art from Russia, Persia, India, China, Japan, and England were imitated to develop designs for silver pieces. Mokume, a wood-grained metal from Japan, was also copied in silver.

Like flatware, silver hollowware has been used for centuries and made for many purposes. There are containers for every conceivable food. Bowls of all sizes and shapes have been made of silver, along with water pitchers, tea and coffee serving sets, sauce boats, cups, goblets, tankards, salt dishes, salt-and-pepper shakers, bread trays and baskets. Containers for cooking or keeping foods hot have been made of silver: chafing dishes, coffee serving sets, and samovars, the Russian urns in which tea is made. Silver vases, candlesticks, and other decorative objects have all been used on dining tables to enhance the place settings and make the meal a special occasion for families and guests.

By the end of the nineteenth century, the United States led the world in manufacturing silverware and purchasing it as well. In the 1890s, as the price of silver bullion kept decreasing and competition among manufacturers increased, silver became sufficiently inexpensive that lower-middle-class consumers could afford to own it.

Like other Continental nations, Scandinavians used silver for fine dining and held it in high regard. Georg Jensen Solvsmedie, a firm in Copenhagen, Denmark, began manufacturing tableware in 1904. Jensen’s modern, clean designs were a change from the rococo and neoclassic designs of the nineteenth century, and, by 1938, the United States was the largest market for Danish sterling silverware. At the beginning of the twenty-first century, there was still a Georg Jensen showroom in New York City.

### SILVER SERVICE

In Britain, a formal type of restaurant service is called “silver service.” Foods are brought to the table in silver-plated serving dishes and platters and are placed on the diners’ plates by the serving staff.

Silver and gold ice cream spoons in the Burgundian style, Germany, circa 1880. The large spoon in the center was meant for serving. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

The purchase and use of silverware, however, have been steadily declining since World War II, perhaps because families are unwilling to spend money on it and have neither the time nor the servants to care for it. Furthermore, many European families lost their silverware during wars and so had none to pass on to the next generation. It is also true that meals have become less formal, and stainless steel flatware and hollowware better-looking and more acceptable, not to mention less expensive, than silver as the twentieth century ended. However, sterling silver is still for sale and is still being collected and enjoyed by those who can afford it.

**SIN AND FOOD.** “Rich as Sin,” “My Sin,” “Sin Pie”—all are recipe names found in community (and church!) cookbooks in the United States today. Initially these may entice the prospective cook or eater with the implied promise of an exceptionally delicious indulgence, so delicious in fact, that it ought to be too good for humans. Behind these sweet temptations, however, is a somber history. Because these foods are too sweet, too rich, too good, humans who eat them go too far. People have long associated food with sin. Although a complex concept that varies throughout human cultures, sin is at its most basic a violation of the boundary between the sacred and the profane. In most religious traditions, food, literally and symbolically, is a vehicle for transgressing limits. As an ancient Babylonian psalmist confessed, “The

food that belongs to god, I have eaten.” This is one side of a powerful paradox. Food has divine origins as other recipes for “Heavenly Hash,” “Angel Food,” and quite literally, “Ambrosia” (food of the gods) attest. It is the means by which life is sustained and through which mortals may commune with the divine and each other. To take food in ways that violate divine intentions, however, can have grave consequences.

In early religions, sin is usually an offense against the cosmic order of things rather than personal disobedience of a god’s command. It is the violation of a prohibition, or taboo, that leads to defilement. To be in right relationship with the cosmos is to be pure or in one’s appropriate state vis-à-vis the cosmos. Religions often have rules about food consumption and preparation that symbolize order on many levels. The Hua of Papua New Guinea, for example, have a complex system of food-related taboos. One should not eat the food of another with whom conflict may exist, as the vital essence transferred in eating may have negative affects. Pregnant women should not eat hard yams lest they induce a hard labor. Young men must avoid foods prepared in certain ways by menstruating women lest they be weakened by them. In each case, the idea of ordered relationships that perpetuate life is reinforced.

The major Eastern traditions, Hinduism and Buddhism, also conceptualize transgression as a violation of order or karma. In the Hindu caste system, offenses are relative to one’s assigned station in life. A Brahman of the highest caste can be rendered impure by eating food touched by a lower caste Hindu. Even Brahman women render food impure if they touch it during menstruation, a time of ritual impurity. Among the major offenses in Hinduism are two general food-related ones. Killing or eating a cow, which is sacred, is forbidden. Drinking intoxicants is also forbidden because it arouses human sensibilities to levels for which they are not intended. Violating either of these proscriptions will lead to a lower state of existence in the next life. In Buddhism, one of the three roots of evil is *lobha*, which has a range of meanings including “craving.” Craving foods, being attached to this existence through them, affects one’s karma negatively. Eating must be done dispassionately lest it lead one out of the bounds of discipline. Conversely, the disciplined consumption of rice and tea have become means to enlightenment in some Buddhist traditions. Some gurus have advanced to such a high spiritual state that they are able to go without eating for long periods, having lost the need for feeding. In their perfectly balanced existence, they are self-replenishing.

Western religious traditions have defined sin primarily as willful disobedience of God’s commandments and the resulting immoral actions. The sense of disorder and taboo remain, however. In Judaism and Islam, dietary codes help to define proper relationship to God. Jews must not eat foods that are *terefah* (unfit). Many foods are unfit because they are hybrids that defy order

themselves. Shellfish are *terefah* because they do not have fins like other fish. To eat such foods is to become impure, separate from God and God’s people. Muslims must avoid *haram* (unlawful) foods. Jewish and Muslim dietary laws overlap somewhat, most notably in the prohibition against consuming pork. Disciplined eating and periods of abstaining from food aid Muslims in their quest to submit themselves to Allah’s will.

The connection between cosmic defilement and offending God also remains in Christianity. Some early Christians, as evidenced most clearly in the epistles of St. Paul, followed classical notions of food as healthy for the body and a licit pleasure to be enjoyed in moderation. For St. Paul, eating meat had nothing to do with one’s spiritual state. Others maintained the Jewish dietary laws or other forms of dietary restriction such as vegetarianism. While the Pauline position won out in normative Christianity, and Christian sects that advocated special diets were often suspected of heresy, the notion that food had nothing to do with one’s relationship to God did not pass into Christianity unchallenged. Gradually, eating became associated with desire that cannot be curbed and seen as an illicit pleasure that distracted from godly matters. And it became connected to that other unruly human urge, sexuality. Some church leaders advocated fasting, especially for women, as a means of curbing sexual desire. Thus celibacy and abstaining from food became hallmarks of Christian purity. Original sin, as St. Augustine came to define it, further connected food, sexuality, disobedience, and disorderliness. Because the first parents, Adam and Eve, ate fruit God had forbidden, every human inherits their lack of control through lust. For St. Augustine, it was the uncontrollable desire for the pleasure of eating, even more than sex, that was most difficult for him to control. So although the paradigm for communion with God in Christianity is a sacred feast, eating has become suspect in the Christian tradition as something mired in the profane and attached to human weakness. This takes many forms. Somewhat like the Eastern gurus, medieval Christian mystics gave up earthly food and fed only on Christ’s body.

Though the “sinful” recipes in church cookbooks are taken lightly by the communities that enjoy them in fellowship meals, a growing movement among evangelical women in the United States encourages them to abandon their sinful cravings for food and strive to be, in the words of Christian dieter Patricia Kreml, “Slim for Him.”

Food is often the central focus of another side of sinning, the failure to consider the needs of others as well as one’s own. Greed, closely associated with gluttony and lust, is railed against in all of the world’s major religious traditions. *Lobha* means ‘greed’ as well as ‘craving’, implying the close connection between transgression against the divine and the community. *Taqwa* (piety), a chief Muslim value, involves the proper fear of Allah and purity of intention, mind, and body. But charity and hospitality toward others are also necessary to *taqwa*. During

Ramadan, a fasting period in which Muslims strive with particular rigor to submit to God, giving food to the poor is also required. Attitudes toward another's feeding reflect one's relationship with the divine. St. Augustine illustrated the human condition in a story about an infant wailing loudly while his brother fed at their mother's breast: "But it can hardly be innocence, when the source of milk is flowing . . . abundantly, not to endure a share going to one's blood-brother, who is in profound need, dependent for life . . . on that food." (*Confessions*, I, vi).

The association between food and sin runs deeply through human cultures, perhaps because eating so clearly involves penetration of boundaries. It is the gift of God that comes from the earth, the sustainer of life through slaughter and harvest, substance that becomes self; and binder of one to another, child to mother, human to divine. Such transformation is mysterious business, not without risks. As anyone who has overindulged at a fellowship meal well knows, too much of a good thing can make food of the gods into devil's food.

**SLOW FOOD.** Slow Food Arcigola, founded in 1989 by Carlo Petrini and known simply as Slow Food, is an international movement headquartered in Bra, Piedmont, Italy, and organized around small, local chapters. Formed in 1986 in opposition to an attempt by McDonald's to place its golden arches in the Piazza di Spagna area of

Rome, Slow Food's mission is to cultivate public appreciation for locally produced foods, wines, and authentic tastes. Pleasure and conviviality at the table are brought into harmony with humane, wholesome conditions of production. The movement encourages opposition to fast food and the fast life to improve the quality of life. While aiming to educate the public's palate, it advocates biodiversity in foods; local food and artisanal production; conservation of traditional foods and foodways and the environments that produce them; and measures to make traditional foods economically viable.

At the beginning of the twenty-first century the Slow Food movement counted sixty-five thousand members in forty-five countries on five continents. Chapters, called *convivia* internationally, numbered 560 worldwide, 340 of which were in Italy, where they are called *condotte*. The group's activities include public education forums, such as guided taste workshops, school programs, and conventions; and publications, such as guides to wines, cheeses, restaurants, food and wine cultures and their histories, and tourism. Slow Food is committed to philanthropy, including *Le Tavole Fraterne* or Friendship Tables; financing solidarity projects; and international charity programs, including sponsoring a soup kitchen in an Amazonian indigenous hospital and a school cafeteria in Sarajevo and rebuilding a cooperative cheese factory in Umbria, Italy, that was damaged in the 1997 earthquake. Through the Ark of Taste projects, begun in 1996, the movement advocates identifying and safeguarding endangered food "treasures," for example, charcuterie, cheeses, grains, vegetables, and local breeds; small, quality food products, such as *lardo di Colonnata*—lard packed in salt and herbs, served in thin slices on bread—and Protected Designation of Origin (DOP) cheeses; and agricultural and food heritage sites, such as, cafés, pastry shops, inns, and restaurants. The Slow Food presidia have focused on these areas to guarantee their economic and commercial futures, to protect the land from degradation, and to create new job opportunities. Small, quality food producers need protection against the industrial food complexes that control ever larger market shares and large-scale distribution. The industrial complexes often influence laws that threaten the very existence of traditional producers.

In the tradition of avant-garde manifestos, *The Slow Food Manifesto* (Paris, 1989) states, "We work towards the rediscovery of the richness and aromas of local cuisines by opposing the leveling effect of the Fast Life . . . which has changed our lives and threatens the environment and landscape." The movement's apt symbol therefore is the snail—small, cosmopolitan, prudent, and slow. The manifesto warns against being "too impatient to smell and taste" and "too greedy to remember what [we] have just devoured." Opposing fast cheap food and the values and systems of globalized food production, Slow Food can be firmly placed in the biocultural ecology movement. The mission statement of Slow Food USA reads:

Recognizing that the enjoyment of wholesome food is essential to the pursuit of happiness, Slow Food USA is an educational organization dedicated to the stewardship of the land and ecologically sound food production; to the revival of the kitchen and the table as centers of pleasure, culture and community; to the invigoration and proliferation of regional, seasonal culinary traditions; and to living a slower and more harmonious rhythm of life.

The success of its agenda and the growth of its membership—attributable to the rise of an ecological consciousness among educated, affluent consumers, that fosters a concern with the quality of foods and their sources—have encouraged Slow Food to expand its publications, such as the *Slow* journal, published in Italian, French, English, and German; and to open offices in Switzerland (1995), Germany, (1998), New York (2000), and to make plans for an office in Paris. The group's highly successful international taste fair, *Il Salone del Gusto*, first held in Turin, Italy, in 1996, is a review of quality food and wine. With the theme of biodiversity, the fair between 5 and 9 November 1998 attracted 126,000 visitors and featured 300 stalls displaying Italian and foreign artisanal food in three halls devoted to charcuterie and cheeses; gastronomy; and pastry, cakes, chocolate, and coffee. Participants experienced tastings, conferences, seminars, and cooking and tasting courses.

The biennial Slow Food cheese fair was first held in September 1997 in Bra, Italy. The 1998 cheese fair was organized as a market devoted to the 127 European DOP cheeses. The Slow Food movement has also organized *Excellentia* for people to experience various wines; *La Settimana del Gusto*, a week of low-cost menus in restaurants throughout Italy to encourage those under age twenty-six to participate in quality food experiences; and *Il Gioco del Piacere*, biennial blind wine tastings attended by over fifteen thousand people.

#### BIBLIOGRAPHY

Slow Food Editore, established in 1989, has produced about sixty publications, largely in Italian, devoted to the pleasures of wine, food, and conviviality. Among its best-known publications are the quarterlies *Slow* and *Slowine*; *Osterie d'Italia* [Taverns of Italy], a guide to traditional eating establishments; *Vini d'Italia* [Wines of Italy], a comprehensive guide to Italian wines with Gambero Rosso; and *L'arca*, the review of the Slow Food presidia project. Slow Food also publishes monographs on cheeses, beers, wines, and oils. Among them are *Formaggi d'Europa* [Cheeses of Europe], which includes the 127 European DOP cheeses; the taste manuals *Dire, fare e gustare* [Saying, doing, and tasting]; and Giacomo Leopardi, *Il piacere del vino* [The pleasure of wine]; Italian regional recipe books, such as Anna Gosetti della Salda, *Le ricette regionali Italiane* [Regional Italian recipes]; books on food history, such as *Il gusto dell'agro* [Savoring the sour], a history of vinegar; tourism books, such as *Venezia: Draghi, santi e capesante* [Venice: Dragons, saints, and scallops]; and reprints of classics, such as Silvano Serventi, *Il cuoco Piemontese* [The Piedmontese cook] (Bra, Italy: Slow Food, 1995), an

eighteenth-century text on Piedmontese cuisine. The Slow Food Web site is available at <http://www.slowfood.com>.

Luisa Del Giudice

**SNACKS.** Throughout human history, the frequency and content of meals has varied. From ancient times, light foods or leftovers were consumed between meals. These tended to be natural, sweet foods that required little or no preparation, such as grapes, figs, or apples. In nineteenth-century America, interest in snack foods shifted from natural foods to prepared commercial foods, with a high salt and sugar content. It is these processed foods that are considered snack foods in the early twenty-first century.

#### Salty Snacks

America's first commercial snack foods were peanuts and popcorn, which were cheap, tasty, filling, and eminently portable. Peanut and popcorn vendors sold their products on the streets, circuses, and fairs, and later at sporting events. One successful peanut vendor was Amedeo Obici, an Italian-born immigrant living in Wilkes-Barre, Pennsylvania. In 1906, he, along with another Italian immigrant, formed the Planters' Peanut Company. They constantly improved their products and packaging. To promote their products, the company adopted "Mr. Peanut" in 1917—a logo has appeared subsequently on almost every Planters package. Both popcorn and peanuts were marketed to children and were connected with children's holidays. These characteristics have become standard for snack foods.

Homemade pretzels were probably sold for centuries before they were first commercially produced in 1861. Pretzels did not become an important national snack until the 1930s, when a machine was invented to automate production. Recipes for potato chips appeared in the early nineteenth century. Under the name "Saratoga chips," they were popularized by George Crum, the chef of the Moon's Lake Lodge in Saratoga, New York. First manufactured by John E. Marshall of Boston in the 1890s, potato chips were sold in barrels but quickly became stale after a barrel was opened. Potato chips did not become popular until the 1920s, when Laura Scudder asked employees to iron two pieces of wax paper to form a bag. This set off a packaging revolution that permitted chips to be sold airtight bags. Corn chips were originally a Mexican snack—cut-up, fried, or dried tortillas. The first-known commercial corn chips were the *fritotes*, which were made from fried *masa* (corn flour) in San Antonio. Elmer Doolin purportedly bought a bag of *fritotes* and then bought the recipe for one hundred dollars. In 1932, Doolin began manufacturing them under the name Fritos. His renamed product was a success, and his sales expanded as far as St. Louis, Missouri. In 1945, Doolin met potato chip manufacturer, Herman W. Lay, who agreed to distribute Fritos, which became popular

## SOME POPULAR SNACKS

**Animal Crackers:** Invented in 1871 by Pennsylvanian David F. Stauffer.

**Baby Ruth:** Introduced in 1920 by the Curtiss Candy Company of Chicago, this candy is filled with peanuts covered with nougat and a chocolate covering.

**Butterfinger:** Introduced by the Curtiss Candy Company in 1923.

**Candy canes:** Developed in Europe and arrived in the United States via German immigrants. Produced commercially in the 1920s, they became popular in the 1950s.

**Cheetos:** Invented by the Frito-Lay company in 1948.

**Chocolat Delicieux à Manger:** Produced by J. S. Fry around 1847, it is thought to be the first handmade chocolate candy bar.

**Cotton candy or floss:** Made by spinning colored sugar causing it to puff into cotton-like strands, became popular at circuses and fairs before 1900.

**Eskimo Pie:** Originally called the I-scream bar, it was created by Chris Nelson in Onawa, Iowa, in 1920.

**Fig Newton:** Invented by Charles M. Roser of Ohio, who sold recipe to what became NABISCO, which first sold them commercially in 1891.

**Fortune cookies:** An American invention started during the early 20th century, probably in San Francisco. They were first commercially manufactured about 1920.

**Hershey Chocolate Bar:** Introduced by Milton S. Hershey about 1900. It is the world's first manufactured chocolate candy bar.

**Jelly beans:** Probable descendent of Turkish Delight. French confectioners developed the process of "panning" necessary to make jelly beans. In America, jelly beans were a penny candy sold by weight. They were not associated with Easter until the 1930s.

**Junior Mints:** Originally produced by James O. Welch Company, the chocolate covered peppermint now a part of NABISCO Confections, Inc.

**Life Savers:** Developed in 1912 by Clarence A. Crane of Cleveland, Ohio. These round, white peppermints have holes in the middle that resemble life preservers on a boat, hence their name.

**Kit Kat:** A chocolate-covered wafer produced by the Rowntree and Company's Chocolate Crisp, it was renamed the Kit Kat in 1937.

**Lollipops and Suckers:** Unclear origin; a machine for making lollipops was developed by Russian immigrant Samuel Born in 1916 in San Francisco, but Wisconsin's Racine Confectioners Machinery Co. claims to have done so in 1908.

**M & M's:** Introduced in 1940. The company's goal was to create a candy that did not melt, and the idea

was said to have originated during the Spanish Civil War, when soldiers ate chocolates covered with a thin layer of sugar candy that prevented the chocolate from melting in the heat. M&M's quickly became the best-selling confection in the world, but the original version did not contain peanuts. Mars introduced M&M Peanut Chocolate Candies in 1954, and they have been a good seller ever since.

**Milky Way:** Introduced by Mars, Inc., in 1923.

**Mounds:** Coconut and chocolate confection was released in 1922 by Peter Paul Halajia of Naugatuck, Connecticut.

**Mr. Goodbar:** Introduced by Hershey, it was a chocolate-peanut based confection released in 1925.

**NECCO wafers:** Hard cylinder-shaped candies released by NECCO (an acronym for the New England Confection Company), first appearing in 1912.

**Nestlé's Crunch:** Released in 1938 by Nestlé, it is a combination of milk chocolate and crisped rice.

**Oh, Henry!:** Introduced by George H. Williamson of Chicago in 1920, it was originally a log-shaped bar with a fudge center surrounded by a caramel and peanut layer and coated in pure milk chocolate.

**Payday:** Manufactured by the Pratt and Langhoff Candy Company in 1932.

**Pez:** Invented in 1927 by Eduard Haas III, of Vienna, Austria, the hard candy is named after the German word for "peppermint." Pez dispensers were invented in 1948.

**Potato chips:** Recipes were published early in the nineteenth century, and were first manufactured in 1890s by John E. Marshall of Boston. Potato chips did not become popular until the 1930s, after a packaging revolution permitted the chips to remain fresh.

**Reese's Peanut Butter Cup:** Introduced by the H. B. Reese Candy Company, the chocolate-covered peanut butter candy was first manufactured in 1928.

**Snickers Bar:** Created by Mars, Inc., in 1930, the candy bar, composed of a combination of peanut butter nougat, peanuts, and caramel encased in milk chocolate, was first marketed in 1930.

**3 Musketeers:** Created by Mars, Inc., in 1932, the candy bar consisted of three levels of chocolate coating and was named after the novel by Alexander Dumas.

**Toblerone:** Invented by the Swiss Theodor Tobler and Emil Baumann, the chocolate-covered almond nougat candy bar was first manufactured in 1908.

**Tootsie Roll:** Introduced in 1896 by New Yorker Leo Hirschfield, this round, chewy candy was named after his daughter who was nicknamed "Tootsie."

**Twinkies:** Invented by a Chicago bakery manager named Jimmy Dewar, the cream-filled sponge cake was first marketed in 1930.

nationwide, and the two companies merged. The Frito-Lay Company introduced Cheetos in 1948, and continued to grow by introducing new snacks and acquire other snack food companies. Owned by PepsiCo. today, Frito-Lay is the largest snack food conglomerate in the world. Many other chip-based snacks have been developed. Some more famous ones include nachos (1943), a snack purportedly developed in Eagle Pass, Texas, and Doritos, first marketed by Frito-Lay (1966).

### Sweet Snacks

Peanuts and popcorn combined to create America's first successful commercial sweet confection. Frederick W. Rueckheim, an immigrant from Germany, combined peanuts, popcorn, and molasses to create Cracker Jack. By 1923 the Cracker Jack Company sold more than 138 million boxes annually. However, sweet snacks had been sold well before Cracker Jack. They fall into four major categories: hard candy, baked goods, chocolate candy, and frozen sweets

Candies have been produced in Asia for thousands of years. Homemade candies, such as lemon drops, jujubes, and peppermints, were produced in Europe by the late eighteenth century. Penny candies were frequently sold in grocery stores. During the nineteenth and twentieth centuries, thousands of candies have been manufactured, including saltwater taffy (1883), first manufactured commercially in Atlantic City, New Jersey, and Life Savers (1912), manufactured by Clarence Crane of Cleveland, Ohio.

The second broad category of sweet snacks are baked goods. Small baked cakes and pastries with sugar had been produced since the late Middle Ages in Europe and likely originated in Arab lands, particularly Baghdad. "Cookies," an American word derived from Dutch, initially referred to sugar cookies flavored with spices. The word was subsequently extended to include other kinds, such as wafers, snaps, and macaroons. Initially, cookies were handmade and were sold in grocery stores. They were first manufactured in the United States in the late nineteenth century. Animal Crackers (1871) and Fig Newtons (1892) were among the first commercially manufactured cookies. Numerous commercial varieties have been manufactured since, such as OREO's, a chocolate sandwich cookie, and gingersnaps. Several chains that bake fresh cookies have emerged in the last quarter of the twentieth century, including Famous Amos' in 1976 and Mrs. Field's Cookies in 1977. Many other baked goods were also converted into commercial snacks. Hostess Cup Cakes were first manufactured in 1919. Twinkies were invented by a Chicago bakery manager named Jimmy Dewar in 1930, and were later acquired by Hostess.

### Chocolate Candy

The third broad category is chocolate-based candy. In 1847 Joseph Storrs Fry, a British Quaker, invented a process of combining cocoa powder, sugar, and melted

Hot dogs make a perfect urban snack food since they are sold on the street, easy to handle, and easy to eat. © PATRICK GIARDINO/CORBIS.

cocoa butter that produced a thin paste which could be shaped in a mold. The handmade *Chocolat Delicieux à Manger* is considered to be the first chocolate bar. J. S. Fry and Company became the largest manufacturer of chocolate in the world. In Switzerland, Henri Nestlé developed the process of making milk chocolate in 1867. Another Swiss chocolate manufacturer, Daniel Peter, used Nestlé's chocolate to make a milk chocolate bar in 1879. A third Swiss, Theodor Tobler, marketed in 1908 his Toblerone, consisting of a triangular chocolate bar with almond-and-honey nougat. Other chocolate-making companies emerged, such as Lindt of Switzerland (1845) and Belgium's Godiva Chocolates (1926).

In the United States, chocolate candy and caramels became important by the 1870s. These were expensive in part because they were all handmade. Boxed chocolates were manufactured by the 1840s. Early chocolate confection makers included the Walter Baker Chocolate Company and Walter M. Lowney Company, both headquartered in Boston. The Whitman Sampler became a national boxed chocolate by 1907. Retail candy stores have developed, including See's Candy (1921) and Fanny Farmer (1919).

The first American to manufacture chocolate bars was Milton Hershey, who in 1903, began to build what would become the world's largest chocolate manufacturing plant in Derry Church (later renamed Hershey), Pennsylvania. Hershey's Chocolate Bars were the first of thousands of chocolate bars to roll off the assembly line, followed by Hershey's Chocolate Kisses in 1907. Hershey produced many new products including Mr. Goodbar, composed of chocolate and peanuts, and the Krackel, composed of chocolate and rice.

Hershey's success encouraged others to produce chocolate bars. Otto Y. Schnering of Chicago founded the Curtiss Candy Company, which released the Baby Ruth candy bar in 1920. Curtiss later introduced the

Butterfinger. George H. Williamson, a salesman for a candy broker in Chicago, opened a candy store and launched the Oh Henry! candy bar in 1920. In the same year, Frank and Ethel Mars of Minneapolis started up Mars, Inc. Three years later they produced the Milky Way candy bar, followed in 1930 by the Snickers Bar, which quickly became America's most popular candy bar—an honor it still holds today. This was followed by M&M's in 1940.

### Frozen Sweets

Ices and ice cream have been produced for centuries. Ice cream parlors probably originated in Italy and France and have sold their goods since at least the late eighteenth century. The three major snack products have all been American inventions: the ice cream cone, ice cream bar, and popsicle. The ice cream cone was invented during the late nineteenth century and was popularized at the St. Louis World's Fair. The cone made it possible to consume ice cream without the need of a spoon and cup. Ice cream parlors have continued to thrive and major chains, such as Carvel's (1934), which serves soft-serve ice cream, and Baskin-Robbins (1948), have become very well known.

Handheld ice cream bars quickly became an important snack food in America. The Eskimo Pie originated in Iowa in 1920. In the same year Harry Burt invented the chocolate-covered vanilla ice cream bar on a stick in Youngstown, Ohio. Ice cream bars became popular during the following decades. The popsicle, frozen flavored water, was first commercially manufactured in the United States during the 1920s.

### Snack Food in the Early Twenty-First Century

Many snacks are heavy on calories, fat, and salt. The term "junk food" was popularized in 1972 by Michael Jacobson of the Center for Science in the Public Interest. The concern with empty calories has continued, and of particular concern has been the targeting of youth by snack food companies. As a response to junk food charges, a natural snack food industry developed during the 1970s. This included such snacks as gorp, composed of various combinations of raisins, peanuts and other natural foods, used by hikers and now available commercially in most grocery stores.

The commercial snack food industry is a major component of America's economy. When the total statistics of commercial candy, baked snacks, chocolates, and frozen snacks are combined, the industry sells annually in excess of \$75 billion of products in the United States alone.

**SOCIOLOGY.** Sociology involves the study of how people relate to each other, as well as how the institutions of society affect behavior and attitudes. For most of the past hundred and fifty years, sociologists have focused mainly on social institutions and structures. It was only around the middle of the twentieth century that they turned their attention to the important roles that technologies (including food production and processing) play in society. Other disciplines (particularly anthropology) have a much longer history of research into food and culture.

Food and food habits have been only implicitly assumed in sociological literature until just recently. Food studies have been an integral part of both rural sociology and medical sociology. For rural sociologists, food has been central in studies of agricultural and technological change. Food has also been a main focus in the studies of farms, community living, social change, and consumer issues. In fact, rural sociologists began to study food production in the 1930s through research on the adoption and diffusion of innovations (new technologies).

For medical sociologists, food and nutrition are now recognized as an important factor in the study of health and wellness. Sociologists examine how our nutritional habits are based on cultural identity, gender, race and ethnicity, and social class. Although food is a fundamental concern for human life, sociologists are now just establishing a sociology of food by identifying how lifestyles, social class, gender, and ethnicity influence food selection and consumption. In fact, much of the market research that food companies conduct is in fact a

form of sociological research (e.g., focus groups, surveys, and interviews).

The sociological study of food is important in understanding social change, the state, and consumer society. For example, positive social change has come about as a result of epidemiological and sociological studies of the importance of sanitation. Sociological studies based on food exportation, importation, and food agricultures have examined how states develop. In addition, research into the inequality of distribution and access to food comprises another way that sociologists can expose to explain class, race, and gender differences, as well as forms of political domination. Food is also important in explaining consumerism, cultural assimilation, modernization, and how beliefs and rituals change.

Sociologists have always been interested in social inequality and stratification (i.e., through analysis of gender, ethnic, and class differences.) For example, some foods are associated with women and some with men. Women eat less food overall, and they are usually light foods or foods that can be nibbled, such as salad or fish. Men tend to eat more food, and prefer foods associated with strength, such as red meat. Food habits also vary significantly with age. For example, soft or strained foods are appropriate for very young children who have no teeth, as well as for the elderly (for the same reason). As people age, they also become more concerned about the role of diet in their overall health.

Food also represents distinctive cultures; for example, pasta is associated with Italian culture, or curry with Indian culture. Cultures evolve to suit the local environment. For instance, spicy foods are more popular in the warmer climates. Class distinctions in foods abound. In the early 1900s in Great Britain, people in the upper classes ate more meat than those of the middle or lower classes. However, by the middle of the century, all people ate about the same amount of meat, as advances in food technology put meat in the range of everyone. Economically disadvantaged groups are sometimes forced to eat what is cheap, and these foods may not be as nutritious as higher-priced foods. Disadvantaged groups then are more vulnerable to health problems, such as heart disease or obesity.

It has been said that “We are what we eat.” Food becomes part of our self-identity. From a very young age, an individual is socialized into his or her adult eating habits. A person eats what his family eats when he is young—these habits do not tend to change that much with age. In Western cultures, young children are taught that the insects they find are not to be eaten. In other cultures, however, young children are taught that certain insects are edible and they become part of the diet. Foods are part of the rituals we use to accept new members into our group, to celebrate milestones, and to express religious or political beliefs. For example, a new neighbor

might be presented with a basket of food or a homemade pie as a welcome gift.

Celebrations, such as birthdays and anniversaries, usually involve some kind of cake or other sweet food. National holidays usually include foods associated with the country. For example, Americans celebrate Independence Day with backyard barbecues (including hamburgers and hot dogs, potato chips and watermelon). Thanksgiving is closely associated with turkey. Religious holidays also use symbolic foods, such as ham at Christmas for Christians. Some religions have specific taboos on food. For instance, Jewish people do not eat pork, while Hindus do not eat beef, and Seventh-Day Adventists do not eat meat at all. Many religions also endorse fasting as part of their rituals.

Sociologists have shown how the level of development within a country influences food habits and preferences. Industrialized countries consume and waste more food than developing countries. Americans may waste up to 25 percent of their food. Waste results from poor storage and processing, as well as from unused leftovers and spoiled foodstuffs that are never used. There is less consumer waste in developing countries. However, this practice is increasing as more countries adopt Western ideas and values concerning food.

Almost every culture has some form of food taboo. In fact, there is only one taboo that is universal, and that is the restriction on eating human flesh. This was not always the case, however. Early people, such as the South American Indians, would grind up the bones of their ancestors into a communal pot, to share their strength and wisdom with all tribal members. Some taboos restrict certain kinds of foods to certain meals. For example, Americans eat cereal for breakfast, but not for dinner. Food taboos may be based on cleanliness standards, but taboos may also be used to change entire food systems. Sometimes it is easier to restrict foods on religious beliefs, than to convince people rationally to change their eating habits. Emotions also play a major role in decisions about what people eat and why. Sociological research and theory are therefore important for understanding how to increase human health through better diet and nutrition.

**SODIUM.** Sodium is normally present in food and in the body in its ionic (charged) form rather than as metallic sodium. Sodium is a positively charged ion or cation ( $\text{Na}^+$ ), and it forms salts with a variety of negatively charged ions (anions). Table salt or sodium chloride ( $\text{NaCl}$ ) is an example of a sodium salt. In solution,  $\text{NaCl}$  dissociates into its ions,  $\text{Na}^+$  and  $\text{Cl}^-$ . Other sodium salts include those of both inorganic (e.g., nitrite or bicarbonate) and organic anions (e.g., citrate or glutamate) in aqueous solution, these salts also dissociate into  $\text{Na}^+$  and the respective anion.

### Types and Amounts of Common Foods that Contain the Recommended Levels of Sodium

Only small amounts of salt or sodium occur naturally in foods, but sodium salts are added to foods during food processing or during preparation as well as at the table. Most sodium is added to foods as sodium chloride (ordinary table salt), but small amounts of other salts such as sodium bicarbonate (baking soda and baking powder), monosodium glutamate, sodium sulfide, sodium nitrate, and sodium citrate are also added. Studies in a British population found that 75 percent of sodium intake came from salts added during manufacturing and processing, 15 percent from table salt added during cooking and at the table, and only 10 percent from natural foods (Sanchez-Castillo et al., 1987). Most sources of drinking water are low in sodium. However, the use of home water softening systems may greatly increase the sodium content of water; the system should be installed so that water for cooking and drinking bypasses the water softening system.

The estimated minimum safe daily intake of sodium for an adult (0.5 grams) can be obtained from  $\frac{1}{4}$  teaspoon of salt,  $\frac{1}{4}$  of a large dill pickle,  $\frac{1}{2}$  can of condensed tomato soup, one frankfurter, or fifteen potato chips. The effect of salt added in processing is noted by the calculation that, whereas one would need to consume 333 cups of fresh green peas (with no salt added during cooking or at the table) in order to consume 0.5 grams of sodium, the estimated minimum safe daily intake of sodium is provided by only 1.4 cups of canned or 2.9 cups of frozen green peas.

Whereas the estimated minimum safe intake for an adult is 0.5 g/day of sodium (1.3 g/day of sodium chloride), average Americans consume between 2 and 5 g/day of sodium (between 5 and 13 g/day of sodium chloride) (National Research Council, 1989). Sodium chloride, or salt, intake varies widely among cultures and among individuals. In Japan, where consumption of salt-preserved fish and the use of salt for seasoning are customary, salt intake is high, ranging from 14 to 20 g/day (Kono et al., 1983). On the other hand, the unacculturated Yanomamo Indians, who inhabit the tropical rain forest of northern Brazil and southern Venezuela, do not use salt in their diet and have an estimated sodium chloride intake of less than 0.3 g/day (Oliver et al., 1975). In the United States,

### BRIEF OUTLINE OF THE HISTORY OF SALT

Common salt is the chemical compound  $\text{NaCl}$ . Salt makes up nearly 80 percent of the dissolved material in seawater and is also widely distributed in solid deposits. It is found in many evaporative deposits, where it crystallizes out of evaporating brine lakes, and in ancient bedrock, where large extinct salt lakes and seas evaporated millions of years ago. Salt was in general use long before history began to be recorded. Salt has been used widely for the curing, seasoning, and preserving of foods.

individuals who consume diets high in processed foods tend to have high sodium chloride intakes, whereas vegetarians consuming unprocessed food may ingest less than 1 g/day of salt. Individuals with salt intakes less than 0.5 g/day do not normally exhibit chronic deficiencies, but appear to be able to regulate sodium chloride retention adequately.

### Recommended Intake of Sodium

The daily minimum requirement of sodium for an adult is the amount needed to replace the obligatory loss of sodium. The minimum obligatory loss of sodium by an adult in the absence of profuse sweating or gastrointestinal or renal disease has been estimated to be approximately 115 mg/day, which is due to loss of about 23 mg/day in the urine and feces and of 46 to 92 mg/day through the skin (National Research Council, 1989). Because of large variations in the degrees of physical activity and in environmental conditions, the estimated level of safe minimum intake for a 70-kg adult was set at 500 mg/day of sodium (equivalent to 1,300 mg/day of sodium chloride) by the National Research Council (1989). Although there is no established optimal range of intake of sodium chloride, it is recommended that daily salt intake should not exceed 6 grams because of the association of high intake with hypertension (National Research Council, 1989). The *Dietary Guidelines for Americans*, published in 2000, include a recommendation to choose and prepare foods with less salt.

Individuals who wish to lower their sodium or salt intakes should use less salt at the table and during cooking, avoid salty foods such as potato chips, soy sauce, pickled foods, and cured meat, and avoid processed foods such as canned pasta sauces, canned vegetables, canned soups, crackers, bologna, and sausages. Individuals should also become aware of and avoid "hidden" sources

of sodium such as softened water, products made with baking soda, and foods containing additives in the form of sodium salts.

The need for sodium chloride is increased during pregnancy and lactation, with the estimated safe minimum intake being increased by 69 mg/day and 135 mg/day, respectively, for women during pregnancy and lactation. The estimated minimum requirement for sodium is 120 mg/day for infants between birth and 5 months of age and 200 mg/day for infants 6 to 11 months of age (National Research Council, 1989); these intakes are easily met by human milk or infant formulas. The estimated minimum requirements of sodium for children range from 225 mg/day at one year of age to 500 mg/day at 10 to 18 years of age.

### **General Overview of Role of Sodium in Normal Physiology**

Total body sodium has been estimated at 100 grams (4.3 moles) for a 70-kg adult. In general, the cytoplasm of cells is relatively rich in potassium ( $K^+$ ) and poor in sodium ( $Na^+$ ) and chloride ( $Cl^-$ ) ions. The concentrations of sodium (and potassium and chloride) ions in cells and the circulating fluids are held remarkably constant, and small deviations from normal levels in humans are associated with malfunction or disease.  $Na^+$ ,  $K^+$ , and  $Cl^-$  are referred to as electrolytes because of their role in the generation of gradients and electrical potential differences across cell membranes. Sodium and sodium gradients across cell membranes play several important roles in the body. First, sodium gradients are important in many transport processes. Sodium tends to enter cells down its electrochemical gradient (toward the intracellular compartment that has a lower  $Na^+$  concentration and a more negative charge compared to the extracellular fluid compartment). This provides a secondary driving force for absorption of  $Cl^-$  in the same direction as  $Na^+$  movement or for the secretion of  $K^+$  or hydrogen ions ( $H^+$ ) in the opposite direction in exchange for  $Na^+$ . The sodium gradient is also used to drive the coupled transport of  $Na^+$  and glucose, galactose, and amino acids by certain carrier proteins in cell membranes; because as  $Na^+$  enters down its electrochemical gradient, uptake of glucose/galactose or amino acids can occur against their concentration gradient. Second, sodium ions, along with potassium ions, play important roles in generating resting membrane potentials and in generating action potentials in nerve and muscle cells. Nerve and muscle cell membranes contain gated channels through which  $Na^+$  or  $K^+$  can flow. In the resting state, these cell membranes are highly impermeable to  $Na^+$  and permeable to  $K^+$  (i.e.,  $Na^+$  channels are closed and  $K^+$  channels are open). These gated channels open or close in response to chemical messengers or to the traveling current (applied voltage). Action potentials are generated in nerve and muscle due to opening of  $Na^+$  channels followed by their closing and the re-opening of  $K^+$  channels.

A third important function of sodium is its osmotic role as a major determinant of extracellular fluid volume. The volume of the extracellular fluid compartment is determined primarily by the total amount of osmotic particles present. Because  $Na^+$ , along with  $Cl^-$ , is the major determinant of osmolarity of extracellular fluid, disturbances in  $Na^+$  balance will change the volume of the extracellular fluid compartment. Finally, because  $Na^+$  is a fixed cation, it also plays a role in acid-base balance in the body. An excess of fixed cations (versus fixed anions) requires an increase in the concentration of bicarbonate ions.

### **Consequences of Deficiency or Excessive Intake Levels**

Sodium balance in the body is well controlled via regulation of  $Na^+$  excretion by the kidneys. The kidneys respond to a deficiency of  $Na^+$  in the diet by decreasing its excretion, and they respond to an excess of  $Na^+$  by increasing its excretion in the urine. Physiological regulatory mechanisms for conservation of  $Na^+$  seem to be better developed in humans than mechanisms for excretion of  $Na^+$ , and pathological states characterized by inappropriate retention of  $Na^+$  are more common than those characterized by  $Na^+$  deficiency.

Retention of  $Na^+$  occurs when  $Na^+$  intake exceeds the renal excretory capacity. This can occur with rapid ingestion of large amounts of salt (for example, ingestion of seawater) or with too-rapid intravenous infusion of saline. Hypernatremia (abnormally high plasma concentration of  $Na^+$ ) and hypervolemia (abnormally increased volume of blood), resulting in acute hypertension, usually occur in these situations, and the  $Na^+$  regulatory mechanisms will cause natriuresis (urinary excretion of  $Na^+$ ) and water retention.

The body may be depleted of  $Na^+$  under extreme conditions of heavy and persistent sweating or when conditions such as trauma, chronic vomiting or diarrhea, or renal disease produce an inability to retain  $Na^+$ . Sodium depletion produces hyponatremia (abnormally low plasma concentration of  $Na^+$ ) and hypovolemia (abnormally decreased volume of blood) which place the individual at risk of shock. Medical treatment includes replacement of  $Na^+$  and water to restore the circulatory volume. If the loss of  $Na^+$  is not due to renal disease, mechanisms to conserve  $Na^+$  and water are activated. Loss of  $Na^+$  can also be caused by the administration of diuretics, which inhibit  $Na^+$  and  $Cl^-$  reabsorption, or by untreated diabetes mellitus, which causes diuresis.

### **Regulatory Processes that Govern the Uptake and Excretion of Sodium**

The kidneys are the main site of regulation of  $Na^+$  balance. The intestines play a relatively minor role. Under normal circumstances, about 99 percent of dietary  $Na^+$  and  $Cl^-$  are absorbed, and the remainder is excreted in the feces. Absorption of  $Na^+$  and  $Cl^-$  occurs along the

entire length of the intestines; 90 to 95 percent is absorbed in the small intestine and the rest in the colon. Intestinal absorption of  $\text{Na}^+$  and  $\text{Cl}^-$  is subject to regulation by the nervous system, hormones, and paracrine agonists released from neurons in the enteric nervous system in the wall of the intestines. The most important of these factors is aldosterone, a steroid hormone produced and secreted by the zona glomerulosa cells of the adrenal cortex. Aldosterone stimulates absorption of  $\text{Na}^+$  and secretion of  $\text{K}^+$ , mainly by the colon and, to a lesser extent, by the ileum.

The kidneys respond to a deficiency of  $\text{Na}^+$  in the diet by decreasing its excretion, and they respond to an excess by increasing its excretion in the urine. Urinary loss of  $\text{Na}^+$  is controlled by varying the rate of  $\text{Na}^+$  reabsorption from the filtrate by renal tubular cells. Individuals consuming diets that are low in  $\text{Na}^+$  efficiently reabsorb  $\text{Na}^+$  from the renal filtrate and have low rates of excretion of  $\text{Na}^+$ . When there is an excess of  $\text{Na}^+$  from high dietary intake, little  $\text{Na}^+$  is reabsorbed by renal tubular cells, resulting in the excretion of the excess  $\text{Na}^+$  in the urine. As much as 13 g/day of  $\text{Na}^+$  can be excreted in the urine.

The most important regulator of renal excretion of  $\text{Na}^+$  and  $\text{Cl}^-$  is the renin-angiotensin-aldosterone system (Laragh, 1985). Sensors in the nephrons of the kidney respond to changes in  $\text{Na}^+$  load by influencing the synthesis and secretion of renin (Levens et al., 1981). A decrease in renal perfusion or  $\text{Na}^+$  load will increase the release of renin. In the circulation, renin acts to initiate the formation of active angiotensin II from angiotensinogen, a protein produced by the liver. Angiotensin II conserves body  $\text{Na}^+$  by stimulating  $\text{Na}^+$  reabsorption by the renal tubules and indirectly via stimulating secretion of aldosterone. Secretion of aldosterone by the adrenal cortex is stimulated by a low plasma  $\text{Na}^+$  concentration and by angiotensin II. Aldosterone stimulates cells of the renal tubules to reabsorb  $\text{Na}^+$ .

Because of the close association of  $\text{Na}^+$  and  $\text{Cl}^-$  concentrations with effective circulating volume,  $\text{Na}^+$  (and  $\text{Cl}^-$ ) retention results in proportionate water retention, and  $\text{Na}^+$  (and  $\text{Cl}^-$ ) loss results in proportionate water loss. Expansion or contraction of the extracellular volume affects the activation of vascular pressure receptors, as well as the release of natriuretic peptides by certain tissues, and result in changes, mediated largely by anti-diuretic hormone (ADH), in renal excretion of  $\text{Na}^+$ ,  $\text{Cl}^-$ , and water. A deficiency of sodium chloride and hypovolemia have also been shown to produce an increase in appetite for salt, which will increase sodium chloride intake.

### **Evidence that Sodium Intake May Be Related to Risk of Hypertension**

Both epidemiological and experimental studies implicate habitual high dietary salt intake in the development of hypertension (Weinberger, 1996). Primary hypertension, or abnormally high blood pressure, is a significant risk

factor for cardiovascular disease, stroke, and renal failure in industrialized societies. Diets that are high in fat, high in sodium, low in potassium, low in calcium, and low in magnesium may contribute to the development of hypertension (Reusser and McCarron, 1994).

Although epidemiological and experimental evidence suggest a positive correlation between habitual high-salt consumption and hypertension, controversy remains regarding the importance of sodium salts in the regulation of blood pressure and the mechanisms by which salt influences blood pressure. This is not surprising, because the response of blood pressure depends on an interplay of various factors, such as genetic susceptibility, body mass, cardiovascular factors, regulatory mechanisms mediated through the neural and hormonal systems, and renal function.

A large comprehensive study on the role of sodium in hypertension was carried out in fifty-two geographically separate centers in thirty-two countries by the INTERSALT Cooperative Research Group (Stamler, 1997). Four centers included in the study had median values for  $\text{Na}^+$  excretion that were under 1.3 g/day. Subjects in these four unacculturated centers had low blood pressure, rare or absent hypertension, and no age-related rise in blood pressure as occurred in populations in the other forty-eight centers in which mean values for  $\text{Na}^+$  excretion were between 2.4 and 5.6 grams  $\text{Na}^+$  per day. Although blood pressure and sodium intake appeared to be associated when all fifty-two centers were included, the correlation between systolic blood pressure and excretion of sodium was not significant when the four centers with the lowest median values of sodium excretion were excluded from the analysis.

Intervention studies of dietary salt restriction to lower blood pressure have produced mixed results. This may be explained by the facts that not all hypertensive patients are salt-sensitive and that many cases of hypertension are due to other causes. Nevertheless, various clinical trials indicate some beneficial effects of dietary restriction of sodium on blood pressure (Cutler et al., 1997; Reusser and McCarron, 1994) with response being greater in older patients, patients with the highest degree of restriction, and in nonoverweight, mildly hypertensive patients.

Researchers are currently attempting to identify the genetic basis of salt-sensitive hypertension and to identify polymorphisms associated with salt-sensitive hypertensive individuals. More than thirty different gene variations could be responsible for essential hypertension, and hypertension is considered to have a complex genetic basis. Further insight into the basis of hypertension may help to determine individuals for whom lowering salt intake would be beneficial and to facilitate the prescription of appropriate drugs.

**SOUP.** A soup is a broth that is infused with flavor. It may be thin and crystal clear like a consommé, voluptuously smooth and creamy like a creamed soup, or so chunky with meat, fish, grains, and/or vegetables that it

Soups play an important role in traditional cookeries all over the world, especially in medical dietetics. Shown here is garlic soup from Nepal. While such preparations may soothe and comfort, the act of heating garlic destroys its antimicrobial properties. © Macduff Everton/CORBIS.

is just this side of a stew. A soup may be the first of several courses, intended just to whet the appetite; it may be one of many dishes served at the same time; or it may be a hearty meal in a bowl. The bottom line is that in order to be a soup, it must be enough of a liquid preparation that eventually one gets around to sipping it, or eating it with a spoon.

Soup is an important mainstay in the everyday diet of most cultures. It was probably one of the earliest cooked preparations because it could be made with just about anything (including leftovers from the day before) and could be extended greatly simply by adding more liquid. Where food is scarce, soup is a staple: The moral of the "Stone Soup" fable is that soup can be made from nothing at all but stones, water, and generosity.

Although classic French cuisine developed as a result of the availability of many types of food and involves many courses, it has also given soup a place of singular

## ORIGINS OF SOUP

While soup is firmly imbedded in most cookeries of the world, the historical situation was somewhat different. Light soups were more generally viewed as adjuncts to medicine, easily digestible preparations employed in feeding the sick, the elderly, or small children. In Africa the stock from boiled greens served this purpose. In ancient China turtle stock was viewed as a potent restorative for the feeble or sick. During the Middle Ages the *iusculum consummatum* was administered in the same manner. Its modern descendant is beef consommé, but in the eighteenth century a concoction of this general class of clear soups was known as a “restaurant” and became fashionable in Paris as a health food. Soon the health food itself lent its name to the place where it was eaten: thus the soup house became the restaurant. During the late 1700s the restaurant quickly evolved from a soup house to an establishment where full meals could be purchased.

English includes several words that provide clues regarding the older meanings of this largely liquid form of food: “soup,” “supper,” “sip,” and “sops,” to name four. The Middle English word *soupen* meant to drink in sips, which is how most soups were consumed by the sick and the elderly. The Old French word *souper*, obviously a parallel term, meant to take an evening meal. In this context the evening meal was presumed to be light, and soup was in fact one way to create a *rechouffé* from the remains of midday dinner. However, the *soupe* itself was

the piece of bread placed in the bowl into which broth was poured. In English this piece of bread was once referred to as the sops, and it was universal practice down to the nineteenth century for country people to put bread in soup before eating it. More fashionable recipes called for toast or even chopped bread fried in butter (croutons), but the essential concept was the same: the moist bread thickened the soup. This custom lingers on in only the most traditional types of recipes, such as French onion soup, where toast or croutons help keep the melted cheese from sinking before the soup reaches the table.

The addition of bread to soup was viewed as inelegant by the end of the eighteenth century—“farmish,” to use the term of the nineteenth-century American cookbook writer Eliza Leslie. Other types of thickeners, especially roux (flour fried in lard or butter) grew in popularity, but so did purees. Puréed cooked vegetables, such as parsnips, turnips, or potatoes (or all three), often appear in Victorian recipes as more healthful substitutes for roux. Roux is largely banned from haute cuisine, and soups are thickened with a wide array of ingredients. Plastic squeeze bottles with tiny nozzles allow cooks to ornament soups with colorful swirls of coulis or intense-tasting herbal sauces. In spite of the emphasis on garnish and appearance, the universal appeal of soup is not its appearance but how it comforts the body.

*William Woys Weaver*

importance. According to the eighteenth-century French gastronome Grimod de la Reynière (1758–1838), “It [soup] is to dinner what a portico or a peristyle is to a building; that is to say, it is not only the first part of it, but it must be devised in such a manner as to set the tone of the whole banquet, in the same way as the overture of an opera announces the subject of the work.” In other words, soup should inspire, set the stage, for the rest of the meal.

Classic French cuisine divides soups into two broad categories: clear soups and thick soups. These classifications are made on the basis of a Western, and specifically French, way of thinking about food that is essentially one of theme and variation. All soups in the “clear” category are prepared using a fundamental technique; variations on and additions to this technique create derivative soups. Once the cook has mastered the basic technique, he or she can make all derivations. One should not assume that other cultures think about food in the same way—in fact, the opposite can be assumed. But since soups from non-

Western cultures fall well within this kind of classification system, it nonetheless seems a reasonable way to approach the topic. Such a system can also be adjusted to embrace ethnic as well as Western cuisines by redefining the categories this way: broth-based soups and thick soups.

### Broth-Based Soups

Broth-based soups are soups made by simmering flavorful ingredients (meats, poultry, seafood, legumes, vegetables, herbs and/or spices) in water or stock to make a thin broth. The broth may then be garnished and seasoned in a variety of ways at the whim of the cook (e.g., with fresh meats and vegetables, herbs, grains or pastas), so that although the broth of such a soup is thin, the soup itself may also be hearty. Stocks are a kind of soup as well: water is simmered with bones, vegetables, and other flavoring agents such as herbs, to infuse the water with their flavor. (In the case of the Japanese stock, *dashi*, the vegetable is seaweed and the flavoring agent dried tuna.)

Unlike soups, stocks are not intended to be eaten on their own. They are a base or ingredient from which to build something more complex—a sauce, a stew, or a soup.

The most famous broth-based soup in the world must be chicken soup, made by cooking chicken in stock or water. Once the chicken is cooked, it may be boned and returned to the soup or eaten separately; then vegetables, rice, noodles, or matzoh balls are added to the soup, depending on the preference of the cook. If the chicken is cooked whole in stock with vegetables, and the resulting broth is served as a first-course soup, followed by the chicken and vegetables, it is called a *poule au pot*—which means “chicken in a pot” and is a meal in itself. If egg and lemon are whisked into the simmering broth until the egg “strings,” and then rice is stirred in, it is the Greek *avgolemono*. Wonton soup (a soup traditionally served at the end of a Chinese meal although a formal dinner may include more than one soup) is made by poaching wontons in a ginger-scented chicken broth; when the broth is seasoned with fragrant lemongrass, kaffir lime leaves (the mildly lemon-tasting and highly fragrant leaves of the kaffir lime), and galangal (a root that tastes something like lavender) and enriched with coconut milk, it becomes the Thai soup *tome kha gai*. An Indonesian chicken soup may be flavored with lemongrass too, saffron or turmeric, and a cooked paste of shallots, garlic, kemiri nuts (a local nut that resembles a macadamia nut), shrimp paste, ginger, and coriander seeds. And if the broth is flavored with a purée of onion, garlic, and tomato, then garnished with crisp, fried strips of fresh tortilla and grated cheese, it becomes the Mexican *sopa de tortilla*.

There are just as many soups based on a beef broth, which may be made from the bones alone, or from an inexpensive cut of beef such as short ribs (which are usually served with the soup) or shin (usually discarded after cooking). French onion soup is one such soup, in which the broth is simmered with well-browned onions until it is sweetened and enriched with their flavor, then poured over thick slices of bread, and covered with a layer of broiled cheese. Onion soup belongs to a genre of bread soups—also broth-based soups—in which broth is poured over bread; the starch from the bread thickens the soup and makes a meal out of it. Bread soups are typically poor man’s food and are likely to be made with water rather than stock. In *Catalan Cuisine*, Colman Andrews mentions a vegetable bread soup made with onions, garlic, sweet pepper, and tomato cooked in a liberal amount of olive oil, and poured over bread. *Ribollita* is another traditional bread soup, from Tuscany, chunky with cabbage and vegetables.

Vietnamese *pho bac* is a noodle soup based on a rich beef broth, spiced with ginger, anise, cinnamon, and chilies and seasoned with fish sauce (a pungent, salty liquid made from fermented anchovy) that is poured over thin slices of raw beef, rice noodles, sliced onion, bean sprouts, and fresh chilies, and garnished with fresh mint

and cilantro. According to Nicole Routhier, *pho* is a traditional breakfast soup. (Throughout much of Southeast Asia, soup may be eaten at any meal and is served along with all main-course dishes.) Korean cooks make a beef soup with browned short ribs, flavored with toasted sesame seeds, soy sauce, garlic, ginger, and scallion; the ribs are then eaten with the soup. Russian borscht and goulash from Hungary are two Eastern European vegetable and meat soups made with beef broth (or probably with water and vegetables alone during lean times). For Japanese *shabu-shabu*, thin slices of beef, onion, cabbage, daikon, and mushrooms are dropped into a pot of simmering water flavored with a piece of kelp, then eaten with a variety of condiments; the flavorful broth—sometimes extended with noodles—is drunk at the end of the meal.

Thin vegetarian soups, like French pistou, are made the same way, by poaching vegetables in simmering water. Then the flavor of the broth is augmented by a purée of basil, garlic, Parmesan cheese, olive oil, and sometimes tomato. South Indian vegetarian cuisine includes a genre of fiery hot soups called *rasams* in which the flavor of the

Soup is also an icon food in some cultures. American alphabet soup assumes a patriotic shape in this clever serving of tomato soup. © TECMAP CORPORATION; ERIC CURRY/CORBIS.

Aside from military rations, canned soup was expensive for most people during the nineteenth century. Shown here is an 1893 advertisement for French-style tomato and mock turtle soups illustrating both the fancy labeling and the tissue wrapping (on the right) which went around the cans to preserve the labels from damage. ROUGHWOOD COLLECTION.

broth is derived largely from spices and then balanced with tomato, lemon, lime, and/or tamarind to add a sour taste. Although *rasams* may be served during the meal, they are also traditionally offered to guests as they enter the house, as a beverage, like tea, in anticipation of the meal to follow.

Seafood soups are almost a category unto themselves because they encompass such a tremendous variety of tastes, textures, and techniques. A simple Western-style seafood soup is made by simmering aromatic vegetables and herbs (and perhaps a bit of cured and/or smoked pork) with water or fish stock, and poaching fish and/or shellfish in the resultant broth. In *Japanese Cooking*, Shizuo Tsuji lists a soup made by poaching shrimp and seaweed in *dashi* seasoned with soy sauce. (Tsuji notes that such “clear” soups are traditionally served at the Japanese table at the beginning of the meal, after the appetizer; more luxurious banquets may include a second soup midway through the meal.) Some thin shellfish soups are made by opening the shellfish in simmering wine, water, or broth, perhaps flavored with aromatic herbs and vegetables. Broth-based seafood soups also include hearty concoctions made with a variety of different types of fish and shellfish poached in a broth. The seafood may be served in the broth, or separately, as in a *bouillabaisse*.

If chicken soup is the most famous broth-based soup, then one of the most elegant (at least in Western culture) must be the *consommé*. A *consommé* is made with a stock that is “clarified,” which means that the stock is returned to the stove, several egg whites are whisked in, and the whole concoction is brought slowly to a simmer. As the mixture heats, the egg white coagulates into a gray-colored “raft” on top of the stock that traps and filters out the impurities that make the stock cloudy. When the

raft is skimmed off, the stock has, almost magically, become perfectly transparent. Finely chopped fresh meat and vegetables are usually added during the clarification process since the egg white seems to rob the stock of flavor along with the impurities. *Consommés* may be served as is, or embellished with any number of garnishes including, at the simplest level, tiny chopped vegetables or herbs, or more complex preparations such as tiny *quenelles*—tender, oval-shaped dumplings of chopped fish, poultry, or meat, bound with egg—or *royales*, tiny, delicate cut-up shapes from a baked egg custard. A *consommé* may be served hot, chilled, or as an *aspic*.

### Thick Soups

Thick soups are soups in which the liquid is thickened—what cooks call “bound”—in one of a variety of ways: by the addition of flour, cream, and/or egg, or by the action of puréeing. Classic French cuisine of the nineteenth and early twentieth centuries was particularly rich in this type of soup, although puréed soups were certainly common in France much earlier than that: The medieval cookbooks *Le Viandier* and *Le Menagier de Paris* include several recipes for puréed soups. An example of a very simple thick soup, achieved by puréeing alone, is a potato-leek soup made by simmering sliced potato and leek in water or chicken broth and then puréeing the mixture—the starch in the potato causes the soup to thicken. Any vegetable soup can be made this way; alternatively, rice, tapioca, pasta, and legumes will also provide thickening when cooked and puréed with the soup.

During the French Revolution, chefs who had made their living cooking for the aristocracy and royalty fled their homeland to other parts of Europe (particularly England) and America, bringing classical French cooking with them. By the late nineteenth century, French chefs were running the kitchens of fine American restaurants, particularly in New York City and Philadelphia, and wealthy Americans were dining in lavish French style. Creamed soups, characterized by a silky smooth texture, made of purées bound with flour and often further enriched with cream and/or egg, belong to this era of luxurious eating. (In 1917 Louis Diat, the French-born chef at the Ritz Carlton hotel in New York City, turned his mother’s home-style, puréed leek and potato soup into a new soup, *vichyssoise*, by puréeing it very finely, enriching it with cream and milk, and then chilling it.) Bisques are a type of intensely flavored creamed soup, typically made with crustaceans such as lobster or crayfish, but also with vegetables, as in tomato bisque. The ingredients are cooked in a broth, then puréed (shell and all, for the seafood, to extract the considerable flavor of the shells), carefully strained, and next creamed. Traditional recipes used bread or rice to thicken the bisque, but that technique is no longer commonly employed.

Finally, chowders and gumbos are another variety of thick, distinctly American, soups. Chowders are soups made with milk or cream; they theoretically contain a

starchy vegetable such as corn or potato. Gumbos are regional American soups from Louisiana, thickened either with a very dark roux—a mixture of flour and fat that is cooked to a deep brown color—okra, or file powder (made from dried sassafras leaves).

**SOUP KITCHENS.** Soup kitchens have been providing nourishment to the poor and hungry since at least the eighteenth century. Though no longer serving solely a fare of soup and bread, they remain an important com-

The Duke of Portland's plan for relieving the stress of the poor, published at Chester, England, in 1799. This is one of the earliest designs for a soup house, or soup kitchen as it is now called. Applicants for food enter at "O" on the plan and stand in line until they reach the money counter at "R." They exit the kitchen at "T." ROUGHWOOD COLLECTION.

ponent of private food relief three centuries later. Patterned after soup societies in Europe, soup kitchens had their genesis in the work of Count Rumford who sought to create a low-cost, nutritionally sound diet for the Bavarian military. He found that the cheapest, most savory, and nourishing food was a soup composed of pearl barley, peas, potatoes, cuttings of fine wheaten bread, vinegar, salt, and water in certain proportions. (He also made a culinary discovery: the crouton.)

Rumford's soups became famous throughout Europe. Originally they were used to feed the military but soon soup houses were established throughout Europe, England and the United States to feed the poor. In London, as many as sixty thousand people were fed daily from Rumford's soup kitchens. The Humane Society of New York City founded one of the earliest soup kitchens in the United States in 1802. Typical of soup kitchens in its day, the Society printed soup tickets that both public and private organizations purchased and distributed to the poor.

I'm spending my nights at the flop-house,  
 I'm spending my days on the street,  
 I'm looking for work, and I find none,  
 I wish I had something to eat.  
 Soup, soup, they give me a bowl  
 of soup, soup, soup. They give  
 me a bowl of soup.

*Depression-era song (1930s)*

Soup kitchens lost their popularity by the 1820s as civic leaders and charity reformers began to believe that indiscriminate handouts encouraged pauperism by destroying self-reliance. New emphasis was placed on reforming the moral character of the poor rather than on feeding them or providing other material needs. As a result only a small number of soup kitchens continued, often only on a temporary basis during unusually harsh economic times. One notable exception to this trend was the Salvation Army's food depots or soup kitchens, which remained in continuous operation after the organization was established in England in the late 1800s.

It was not until the Great Depression that there was resurgence in soup kitchens. Along with breadlines, soup kitchens became a daily part of the life of millions during the 1930s. They were immortalized in numerous poems, songs, and stories. Their heyday, however, waned as government income support and food assistance programs were established. In the early 1980s, when numerous reports of increased hunger surfaced, soup kitchens once again opened in large numbers.

Soup kitchens have become an integral part of a larger, ongoing, emergency food and hunger network. Known as emergency food relief (EFR) programs, soup kitchens and food pantries dominate the private sectors effort to feed the hungry. Soup kitchens usually prepare and serve meals on-site to individuals and families, while food pantries provide a package of several days worth of food for home preparation. It is estimated that between twelve and twenty-one million people each year rely on soup kitchens and food pantries. Second Harvest, the largest private food distribution program, is a national network of two hundred regional food banks providing food to more than 94,000 local soup kitchens, food pantries, and other food programs throughout the United States.

The modern soup kitchen meals are typically free and unlike public food assistance programs often do not have income or other eligibility requirements. The majority of soup kitchens are affiliated with larger nonprofit organizations, most often that of churches, which usually

supply the facility and equipment, financial resources, food and volunteers to staff the operation. Additional resources, most often in the form of food, are obtained from the local food bank, government commodity distribution programs, community retail outlets, and community food drives. Many soup kitchens extend their assistance beyond feeding to include such services as information and referral to other social assistance programs.

Soup kitchens are usually opened on weekdays, typically serving lunch or dinner, but rarely both. They serve a diverse group of people, including homeless, unemployed, working poor, public assistance recipients, elderly, and people with health problems and disabilities. People often rely on these programs as a daily source of nourishment for many months, even sometimes several years. The limited information concerning the nutritional status of people relying on soup kitchens indicates that many frequently experience hunger despite their use of soup kitchens. Often the soup kitchen meal is their only daily meal.

Unlike in the past, soup kitchens serve a variety of meals often consisting of sandwiches or such casserole dishes as stews, tuna noodle casserole, macaroni and cheese and pasta with tomato sauce. Beverages most often served are coffee, tea and fruit drinks. If fruit or vegetables are offered, they are most often canned and rarely is fresh produce served. Desserts are often served and typically comprise cakes, cookies, donuts and pies. The scarce research on the nutritional quality of soup kitchens

## PROFILE OF COUNT RUMFORD

Count Rumford, who was responsible for popularizing soup kitchens, is also credited with the invention of the cooking range, double boiler, and drip coffee pot, among other items now commonplace in the kitchen. Born Benjamin Thompson in Woburn, Massachusetts in 1753, he was a loyalist during the American Revolution and immigrated to Europe after independence. Leopold of Bavaria commissioned him to build an efficient and disciplined Bavarian Army. As part of his effort, Thompson discovered that by enclosing a cook fireplace it could cook food faster and more evenly. This invention became known as the kitchen range. He also invented cooking pots and pans to prepare large quantity meals. Prior to these inventions, each soldier was allotted a certain amount of food that he had to cook over a small fire for himself. For his work, the Bavarian government gave Thompson the title Count Rumford.

## SALVATION ARMY'S SOUP KETTLE

The soup kettle tended by a volunteer ringing a bell is a well-known symbol of the Salvation Army visible at Christmas time. Legend credits the origin of this practice to an incident in December 1894. Survivors of a shipwreck near San Francisco had been taken to a nearby Salvation Army post. Seeing that the soup was almost gone, a volunteer took the huge black soup kettle from the kitchen and affixed a sign to it that read: "Keep this kettle boiling." She then placed the kettle and sign on a street corner and stood by it ringing a bell to attract people. Within a short time passers-by tossed in enough money to buy plenty of food for the victims of the shipwreck. Ever since, Army volunteers have rung bells and stood by kettles.

meals indicates that the vitamin and mineral content of meals varies widely among kitchens and that several nutrients may be consistently below recommended guidelines. The nutrients most often found lacking are calcium, vitamin D, vitamin B<sub>6</sub> and vitamin B<sub>12</sub>. In addition, riboflavin and iron may be inadequate for women of child-bearing age. Foods from the dairy group and in particular milk, all excellent sources of vitamin D, calcium, and riboflavin, are rarely served in soup kitchens. Dark green leafy vegetables, such as spinach or kale, rich in folate and vitamin B<sub>6</sub>, are rarely served. And a full portion of meat, an excellent source of iron and vitamin B<sub>12</sub>, is rarely served. Meats are most often served in small portions in casseroles. Meals may also be high in fat and sodium as they serve highly processed and canned foods.

Throughout their history soup kitchens and other emergency feeding programs have frequently been met with opposition. In the early years, critics claimed that soup kitchens encouraged pauperism and contributed to the moral decay of individuals. Contemporary critics claim that, at best, soup kitchens provide a short-term band-aid remedy to hunger but do not get at the root causes of hunger such as poverty, low wages, and affordable housing. Many soup kitchen supporters concede that their approach may offer only a short-term response to hunger, but they argue it plays a vital role in trying to meet immediate food needs of the poor.

**SOUTH, THE (UNITED STATES).** See **United States.**

**SOUTH AMERICA.** South America is a continent composed of twelve countries and one French colony. The Spanish-speaking countries are: Argentina, Bolivia, Chile, Colombia, Ecuador, Paraguay, Peru, and Venezuela. (Portuguese-speaking Brazil is treated separately in this encyclopedia.) The former colonies of Guyana and Suriname use English and Dutch, respectively, as their official languages, although many in their populations speak indigenous languages. The same can be said for the French colony of Guiana, the home of the cayenne pepper, where French is the official language. The geography of South America is even more varied than that of North America, with long coastlines, lowlands, highlands and mountains, and tropical rain forests. The climate varies from tropical, lying as the continent does across the Equator, to alpine in the high Andes, the backbone of the continent.

The cookery of South America reflects this rich diversity of culture and geography. The indigenous cookeries of pre-Columbian South America have gradually merged with imported cuisines from Europe and Asia. While the Spanish and Portuguese conquistadors introduced their own culinary traditions to the native peoples of South America, indigenous ingredients changed the cuisines of the Old World. The South American contributions included chocolate, vanilla, maize (corn), hot peppers (called *ají* in South America), guavas, sweet potatoes, manioc (cassava), tomatoes, potatoes, avocados, beans, squash (particularly the ancestor of zucchini), peanuts, quinine, and papayas, as well as turkeys.

Maize plays a key role in the cuisine of South America, and it is genetically different from the maize now grown in the Old World, manifested most obviously in its characteristically large kernels. The potato is another vegetable indigenous to South America that has played an important role in cooking worldwide. There are also many vegetables in South America largely unknown beyond the continent, including *ahipa*, *arracacha*, *maca*, *yacón*, *olluco*, and *oca*.

The demographics of South America are critical for understanding the diversity of its cuisines. In countries

like Bolivia, Ecuador, and Peru, the indigenous populations predominate, and their foods and foodways are the most important cuisines. In contrast, Argentina's cookery was heavily influenced by a large European immigration dominated by Spaniards and Italians. Throughout South America, there is also an African influence due to the slave trade, which has added to the culinary mix.

## Venezuela

Venezuela was discovered in 1498 by Columbus when he found the mouth of the Orinoco River. In 1499 the Venezuelan coast was explored by Alonzo de Ojeda and Amerigo Vespucci. Vespucci, coming upon an island in the Gulf of Maracaibo, called it Venezuela because, according to legend, the native villages were built above the water on stilts. Venezuela rises from lowlands to highlands with coffee plantations ascending to the white-capped Andean peaks. It has a mild climate due to its proximity to the Caribbean. Caracas, Venezuela's capital, is the cultural, commercial, and industrial hub.

**Local dishes.** Venezuelan cuisine relies heavily on maize. The two most important preparations are *hallacas* and *arepas*. *Hallacas*—traditionally eaten during holidays, especially Christmas—are boiled dumplings wrapped in banana leaves, but there are innumerable variations, depending on region and family tradition. *Hallacas* are made with a dough made of maize flour mixed with water, which is then filled with meat, vegetables, and spices. *Arepas* are versatile flatbreads, also made of maize flour, that can be baked, grilled, fried, or steamed and served either sweet or savory.

Black beans, called *caviar criollo*, are a Venezuelan favorite. They are served with *arepas* and are also part of the national dish, *pabellón caraqueño*. A hearty dish, it is said to resemble the national flag (*pabellón*), because of the colors of the beef, beans, rice, and plantains in it.

The most popular fish in Venezuela is *pargo*, a red snapper found in semitropical waters, which is a member of the family Lutjanidae. Imported salt cod, brought to the region by the conquistadors, is also important in the cuisine. A favorite dish throughout South America is chicken with rice, but in Venezuela cooks add olives, raisins, and capers to the rice.

*Arequipe*, milk pudding (milk cooked with sugar until very thick), is a favorite dessert in Venezuela, as it is throughout South America. It has different names in different places, but is perhaps best known in the United States as *dulce de leche*.

The traditional beverages of Venezuela are *chicha*, made of fermented maize, and *masato*.

## Colombia

Colombia has two coastlines, one on the Pacific and the other on the Caribbean, that provide the country with a large choice of seafood. Colombia rises from the Pacific

coast through a series of plateaus to the capital, Bogotá. Colombian cooks have a wide range of foods to choose from, including bananas and plantains, papayas, sugarcane, avocados, potatoes (especially in the Andes), and such tropical root vegetables as the sweet potato, taro, cassava (manioc), and *arracacha*. Apricots, pears, grapes, apples, and peaches all grow in Colombia as well.

**Local dishes.** In Colombia, coconut milk is used with great imagination in cooking fish, for example, herring simmered in coconut milk. One very popular soup is *sancocho de pescado*, a fish stew consisting of a variety of ingredients such as plantains, manioc (cassava), herbs, and coconut milk. Stews, usually served with rice, are the preferred way to cook meat, usually beef, especially with vegetables and fruits. Another traditional dish is *gallineta en barro*, an unplucked guinea fowl marinated in spices and lime juice and wrapped in an envelope of clay. It is then buried in hot coals and baked for approximately two hours. When the clay shell is broken, the skin is clean and golden brown and the meat is tender and flavorful.

During colonial times, sugarcane was introduced in Cartagena, one of the most important port cities in the Spanish empire. Due to its wealth as a mercantile city, Cartagena became a center of luxury cookery in which sugar figured as the main ingredient. Modern Colombia has inherited this rich confectionery tradition.

## Ecuador

Ecuador, as the name implies, straddles the equator, which can be reached from the capital, Quito, in about half an hour. Home to two ranges of the Andes, Ecuador is quite mountainous, although the hot and humid Pacific coast lies to the west of the Andes and the rain forest falls largely to the east. Quito (elevation ten thousand feet) is known all over the world for its architectural beauty and cultural refinement. Unfortunately, for outsiders the elevation can cause discomfort. The city lies within a short distance of the extinct volcano, Pichincha. On clear days, a ring of eight volcanoes can be seen from Quito, among them the fabled Chimborazo and Cotopaxi.

**Local dishes.** Ecuador has two cuisines: a highland cuisine of the Andes and a lowland cuisine of the coast. Potatoes, indigenous to the Andes, play a central role in Ecuadorian highland cooking, and its magnificent vegetables and fruits are used liberally in recipes. *Locro*, a thick potato and cheese soup, is sometimes served with avocado slices. Another popular soup, *sopa de maní*, is made from peanuts. Peanuts also figure in *salsa de maní*, a dip consisting of unsweetened peanut butter, hot peppers (*aji*), achiote (annatto), tomatoes, lime juice, garlic, and onions. The paste is also used to flavor meats and vegetables.

Fish is plentiful and most commonly prepared as seviche. One popular seviche from the coastal city of Guayaquil consists of shrimp, *aji*, and vegetables marinated in

lime juice. Once the shrimp are ready to serve, they are garnished with toasted corn kernels (*cancha*), which add an interesting texture and flavor. Stews are popular in the highlands. The spicy and flavorful pork stew, *seco de chancho*, is colored with achiote oil and cooked with beer.

Although the people of Ecuador mainly eat fruit as dessert, a richly flavored pumpkin (or winter squash) cake is very popular.

## Bolivia

Bolivia, a high landlocked country in central South America, is bordered by Argentina, Brazil, and Peru. The famous Lake Titicaca, between Bolivia and Peru, lies at 12,500 feet. Legend has it that an island in the lake is the ancestral home of the Incas. Near the lake's southeastern end are the ruins of Tiahuanaco, a pre-Incan city. After the conquest, Bolivia became part of Peru and was known as El Alto Peru, highland Peru. With independence, the name was changed to Bolivia to honor the liberator, Simón Bolívar.

**Local dishes.** Bolivians like their food hot, and *ajíes* (hot peppers) are widely used. In addition to familiar grains like wheat and corn, quinoa, an indigenous grain that the Incas called “sacred mother grain,” is still commonly consumed. The Spanish prohibited the cultivation of quinoa, but it never entirely lost its appeal to the native population. It is hardy and well suited to poor conditions, such as cold weather and high altitudes. Beef and pork, introduced by the Spaniards, are important foods, as are farm-raised guinea pigs (*cuy*s), a native dish popular in Bolivia and Peru. In the native culture of Bolivia, the potato played such a significant role that it was used for predicting the future, among other things. In fact, Bolivians categorized potatoes as male or female, depending on their shape, and were used accordingly in their cuisine.

In Bolivia, many food traditions remain from pre-Columbian times. One of the relics of the Inca empire is *chicha*, a popular alcoholic drink made from fermented maize.

## Argentina

The second largest nation in South America, Argentina extends from the subtropics to Tierra del Fuego. Although now a separate country, Argentina was once part of the Viceroyalty of the Río de la Plata (River Plate) with Uruguay. The pampas are primarily cattle country and famous for ranching and farming, but this fertile land also produces good crops and fine wine.

**Local dishes.** Finger foods are very popular and are served in cafés, called *whiskerías*, that evolved from tea shops. Empanadas, stuffed pies, are popular throughout South America, and in Argentina they come in various sizes and are eaten as hors d'oeuvres, for light lunches, or with cocktails. One popular filling combines meat and fruit.

Meat is grilled or prepared in stews (*carbonadas*). The Argentines are fond of combining meat and fruit in their stews, but the most famous meat dish is *churrasco* (barbecue), beef, with large salt crystals embedded in it for flavor, is marinated in spices and lime juice and grilled on spits over an open fire. *Viscacha*, a large wild rabbit or hare, is also appreciated on the pampas. Although the focus is on meat in Argentina, excellent fish are harvested from the waters off the coast and prepared in all the usual ways, including sevicehe and *escabeche* (pickled fish).

*Dulce de leche* (milk pudding) is particularly popular in Argentina and throughout neighboring Chile and Uruguay.

*Maté*, also called *yerba maté*, a popular tea in Argentina, is made from the dried leaves of the evergreen, *Ilex paraguariensis*, which is indigenous to South America. The name comes from the Inca word for the calabash that was used as a container. *Maté* can be served either hot or cold.

## Chile

A long, narrow country stretching down between the Andes and the Pacific Ocean, Chile is noted for its copper mines as well as for its wines. The cold Humboldt Current gives Chile the most unusual seafood in the world, including the *erizo de mar* (sea urchin) and *locos* (abalone). The middle third of the country, where table and wine grapes and other fruits and vegetables are raised, enjoys a temperate climate and is very fertile. Seafood and vegetables and fruits are more important in the diet than meat because of the relative lack of land for grazing. Because the seasons in the Southern Hemisphere are the reverse of those in the Northern Hemisphere, so-called winter fruits—apples, pears, and grapes—are exported to North America.

**Local dishes.** Empanadas, often served with the local wine, are popular. Chileans like soups, and, since their fruits and vegetables are plentiful and particularly good, and are enjoyed raw or cooked, many are used for soup—cabbage, for example, and tomatoes. Fish and shellfish are plentiful along the coast and are cooked every conceivable way. One of the finest fish is *congrío*, the conger eel, unique to Chilean waters. Chicken and guinea pig, both raised at home, are family fare. Meat is not so popular, though Chilean meatballs, made with veal rather than beef, are very special.

The fertile soil produces beautiful fruits, which make admirable desserts. *Pisco*, a powerful brandy made from grapes, is served both as an aperitif and as an after-dinner drink.

## Uruguay

A wedge of a nation tucked between Brazil and Argentina on the Atlantic coast, Uruguay is one of the smallest countries in South America and, after Ecuador, the most densely populated. The climate is generally warm, with

Roasting meat on an open fire in the province of Buenos Aires, Argentina. This is the classic Argentine beef *churrasco* in its most rustic form. © HUBERT STADLER/CORBIS.

an even distribution of rainfall throughout the seasons. Rolling grasslands of black, potash-rich soil make raising cattle and sheep the lifeblood of the nation's economy, and roads are edged with fenced driveways for livestock. The capital, Montevideo, is home to a large percentage of Uruguay's population. Much of its industry is centered on processing wool, meat, and hides.

**Local dishes.** Like other South Americans, Uruguayans favor soups and stews. The Atlantic supplies some seafood, and the River Plate (Río de la Plata) is a source of freshwater fish and large frogs, both often used for soup. Meat remains paramount, however. Beef and lamb are grilled as well as braised. *Albóndigas*, fishballs or meatballs, are very popular, particularly when served with a barbecue sauce enriched with wine. *Humitas*, a seasoned corn puree, is sometimes steamed in corn husks, like tamales.

Fresh fruit is abundant and popular for dessert, especially *feijoa* (also called "pineapple guava"), an egg-shaped fruit with a wonderful perfume.

Gin Fizz (pronounced "jeen feez"), as made in Montevideo, has been described as the great glory of Uruguayan drinks. The secret probably lies in the delicate flavor of the local lemons and limes.

## Paraguay

A small landlocked country, bordered by Bolivia, Brazil, and Argentina, Paraguay is known as much for its arts and culture as for its food. Asunción, the capital and by far the largest city in Paraguay, is also the cultural cen-

ter of the country. The landscape is quite diverse, with lush grasslands, rolling hills, and dense forests, as well as the Chaco prairie in the west. Cattle raising and the industries associated with it are economically significant. Guaraní, the local Indian language, and Spanish are the primary languages of the country, although most Paraguayans learn Guaraní before Spanish.

**Local dishes.** In Paraguay, manioc (cassava), the staple food, is consumed at least twice a day, but maize is also important in the diet. Soups and stews, whether vegetable-, beef-, or fish-based, are quite popular. *So'o-yosopy* (*sopa de carne* or beef soup) is more of a stew than a soup; it is so robust that little more is needed than a light dessert to make a complete meal. It is usually accompanied with *sopa paraguaya*, which is not a soup at all but a cheese cornbread that is also served with grilled meats. Very good fish are harvested from the Paraguay River, particularly *dorado*, a firm-fleshed white fish.

Bananas are widely used in Paraguay, fresh and cooked in desserts. *Tereré* is a refreshing tea mixed with cold water and aromatic herbs such as mint, traditionally drunk during the midmorning or early afternoon break for relief from the heat. *Maté* (also *yerba maté*), which has a great deal of caffeine, is pleasantly stimulating and traditionally drunk in the morning.

## Peru

The Andes, which rise from sea level on the Pacific coast to 22,500 feet, dominate this country. Peru was once the center of the Inca Empire, which extended more than

Vendors selling potatoes in the market at Saquisilí, Ecuador. Ecuador is home to some of the oldest potato varieties in the New World. © CARL & ANN PURCELL/CORBIS.

2,500 miles along the Pacific coast of South America. The capital, Lima, is on the coast. Most of the people of the empire were Quechuas. Although the term “Inca” is commonly used to describe the people of the empire, “Inca” originally referred only to the emperor. The Incas terraced and irrigated a difficult terrain, and built roads to link the parts of the empire, enabling farmers to come to town with their produce. The architecture of the Incas is known for its great size and skillful construction. Machu Picchu, one of their most famous cities, stands on a heavily forested mountaintop in the Andes. The Incas were also well known for their administrative skills.

The Incas cultivated thousands of varieties of potatoes many thousands of years ago, and figured out ways to preserve them at high altitudes, either by drying or freeze-drying. The Quechuas also raised quinoa, a hardy plant that thrives where corn cannot grow. The Quechuas had few animals except for the cameloids (the llama and the alpaca) and the *cuy* (guinea pig). The *cuy* is an excellent food animal, and the llama provides wool, leather, fat, and dung for fertilizer, fuel, and building material, as well as meat. Llama meat is made into ham, and *charqui*, or dried llama meat, has remained popular among the native population.

**Local dishes.** Peru has a real food culture. Peruvians like to eat at home and on the street. For example, in Lima the best place to buy *anticuchos* (skewered beef heart) is from stalls outside the *plaza de toros*, built in the 1700s. At home, they make an excellent hors d'oeuvre. Fish and shellfish are enormously popular on the coast and are prepared in myriad ways, including seviche. Along the shore, *cebicherías* serve fresh sevice night and day. Fowl have been known since pre-Columbian days, and the Quechuas knew how to freeze-dry duck. Turkey is very popular, especially for special occasions. The Europeans brought their domestic animals with them, and these have had enormous impact in Peru and elsewhere in South Amer-

ica. Besides grilled meats, Peruvian city folk are fond of *chicharrones*, pork rinds fried in lard, sold by street vendors.

In addition to potatoes and the local large-kernel maize, Peruvians cultivate many other vegetables, including a number of special hot peppers (*ajíes*), which they use in soups and stews, often serving them alone as well. Although Peruvians like sweets—homemade puddings and cakes, store-bought pastries, and convent sweets (although that tradition is dying out in Peru)—they are generally prepared and eaten outside the home, as they are in Europe. Dessert at the end of a meal is more likely to be fresh fruit. *Pisco*, the potent Peruvian brandy, is enjoyed straight or in a *pisco* sour.

## SOUTHEAST ASIA.

*This entry includes three subentries:*

Indonesia, Malaysia, and the Philippines

Thailand

Vietnam

### INDONESIA, MALAYSIA, AND THE PHILIPPINES

Since cuisines are born on the land and grow within its climate, contours, topography, and geography, Indonesia, Malaysia, and the Philippines have bred sister cuisines that find similarities as well in Thailand, Vietnam, Laos, Cambodia, and Brunei Darussalam. It is thus possible to speak of Southeast Asian cuisine even while acknowledging the regional differences that come from history, society, and culture.

Indonesia, for example, with its fifteen thousand islands, covers a large portion of Southeast Asia, and in the early twenty-first century its population (209.4 million) ranked fourth among the world's most populous nations. Although the islands vary greatly in size, climate, and soil and thus in cuisine, it is possible to speak of pan-Indonesian culinary traditions, to set them in their regional contexts, and to invite comparisons with their neighbors.

Malaysia is contiguous to Singapore on one side and to Brunei on the other. Its land, weather, and geographical features are similar to those of the rest of Southeast Asia. However, its population (23 million) is composed of Malay Muslims, Peranakan or Straits Chinese with roots in South China, and Indians, mainly from South India, so it developed three principal cuisines, Malay, Indian, and Chinese. The country's leaders emphasize its multicultural nature and consider all three cuisines equally national.

The Philippines (population 75.8 million), with seven thousand islands, many of them small, has the longest discontinuous coastline in the world. With its tropical weather, plains and mountains, and wealth of water sources, it developed a culinary pattern similar to those of Indonesia and Malaysia. History and the colonial experience, Spanish for almost four hundred years and American for forty years, mediated and transformed its basic Asian cuisine.

Indonesia, Malaysia, and the Philippines therefore demonstrate cuisines that grew on virtually the same soil and in analogous weather conditions but which developed individual, regional characteristics through the actions of history and society on the countries' cultures. Certain similarities and commonalities stand out, however, even before the differences.

### Rice

Meals in all three countries assume the presence of rice, without which the repast is not a meal but a snack,

*pangtawid gutom*, just to bridge hungers, Filipinos say. To the native varieties modern research, for example, that conducted by the International Rice Research Institute (IRRI) in the Philippines, has added high-yield, pest-resistant strains. But Asians treasure traditional strains for their fragrance, particular characteristics, and lore.

Deep from mythic history come the rice stories. The Bagobo people of Mindanao talk of the hero Lumabat, who wished to explore the sky with his sister Mebuyan. She refused, sitting firmly in a rice mortar, which sank into the earth with her as she scattered handfuls of rice. She has stayed underground since then. In a Javanese story Tisnawati, daughter of the supreme god Batara Guru, falls in love with a mortal, Jakasudana, of whom her father disapproves. The father punishes her disobedience by turning her into a rice stalk, but then, in pity, he transforms Jakasudana as well. Their marriage is reenacted by the Javanese harvest ritual in Malaysia.

The cooking of rice proceeds in similar ways. It is washed, cooked in water (steamed, boiled, or parboiled), and made the background and taste-shaper of Southeast Asian meals. Because of its mildness, rice invites contrasting tastes, the hot curries of Malaysia, for example, the chili-hot *sambals* of Indonesia, or the salty preserved fish (*tuyo*, *daing*) of the Philippines. It can be fried, as in Indonesian *nasi goreng* and the morning-after garlic-flavored Philippine breakfast rice (*sinangag*). Malaysians cook rice in coconut milk for the favorite breakfast dish *laksa* and cook thick coconut milk with fragrant herbs until it becomes oil to make *nasi ulam*, which the writer Sri Owen calls a Malaysian version of the British-Indian kedgeree.

All throughout the region, of course, rice is the basis of cakes and other snacks. Glutinous rice cooked in coconut milk with sugar or salt, sparked by ginger, appears everywhere, bare in bamboo baskets; layered, var-shaped, or colored; wrapped ingeniously in coconut fronds, banana leaves, or other leaves; and in fresh and artful native packaging designs. *Kue bugis* are Indonesian steamed-rice cakes filled with sweetened grated coconut and cooked in banana leaves. Malaysia has *kui wajek*, a pudding of glutinous rice, coconut milk, palm sugar, and knotted pandanus (screw pine) leaves and tapeh, fermented glutinous rice with sugar.

The word *suman* is used in the Philippines for many kinds of steamed, leaf-wrapped glutinous rice rolls eaten with grated coconut and sugar and sometimes with ripe mangoes. *Bibingka* is a flat, golden rice cake cooked with coals above and below, and *puto* refers to innumerable steamed cakes of rice flour, some small and round, others platter-sized or cylindrical. A traditional Christmas food is *puto bumbong*, a violet-colored rice (*pirurutong*) steamed upright in bamboo tubes.

Rice is also cooked soft as a porridge, congee, snack, or breakfast food. Filipinos, who inherited rice directly from Chinese traders and migrants, serve it with condi-

ments, such as minced vegetables, shredded meat, chopped nuts, and century egg slices; plain, especially for children and the sick; or cooked with fish, chicken (*arroz caldo* or rice soup), or tripe (*goto*) and served sprinkled with browned garlic, green onions, fish sauce, and lime juice. In a dish learned from Mexico, rice is also cooked with chocolate (*champurrado*) and served with bits of salted fish or dried venison.

Malaysian *kai cheok* is a rice porridge with shredded chicken meat, crisp-fried shallots, a little oil, pepper, shredded ginger, spring onions, and light soy sauce. Indonesia has a chilled rice soup made from soft-cooked rice with fresh coconut milk and small slices of sweet papaya that is served for breakfast or as a cool summer refresher.

The main dishes range through the region's favored flavors, including the Indonesian *sambal goreng udang* of prawns or shrimp and rice; the Hainanese chicken rice of Singapore and Malaysia with its soup, rice steamed in broth, and sauces hot and otherwise; and the Philippine *bringhe* of glutinous rice, coconut milk, chicken, and Spanish chorizo. Rice as staff of life—food for principal meals and for snacks, food for rituals and celebrations, food that shapes tastes and dietary patterns—certainly is a common denominator in Southeast Asia.

### The Coconut

The “tree of life” is shared by Southeast Asia and the Pacific Rim. From Hawaii and Tahiti and all through mainland and island Southeast Asia, coconuts are grated, often on beautiful graters of folk design, and squeezed in water for the “first milk” or cream then again for the thinner milk, for which there are specific uses in dishes.

The milk is thick when used in *rendang*, the Minangkabau dish of buffalo meat or beef cooked long and spicy with shallots, garlic, ginger, turmeric, chilies, and *laos*. The dish can keep for months because the milk turns to oil in the course of cooking. The Malaysian *kambing korma* or lamb curry is mutton or lamb cooked in spices and thick coconut milk. The Javanese *pepes ikan*, on the other hand, is fish wrapped in banana leaves with herbs, spices, and desiccated coconut soaked in warm water for five minutes (not squeezed). The Philippine Bicol region is known for many dishes of meat (beef, chicken, pork), fish, shrimp, and vegetables (*santol* pulp, young jackfruit, chilies) cooked in coconut milk that is thick or thin or both.

Young coconut is also used. In Laguna province in Luzon it is cut in strips and sautéed like noodles or steamed with river shrimp in coconut water. In Iloilo Province in the Visayas it is cooked with chicken into a soup called *binacol*. Young and mature coconuts, including the “sport” coconut, called in Filipino *makapuno*, full, because it is flesh filled, make possible a stellar parade of candies and sweets, including the Philippine *bukayo* (coconut candy) and sweet *makapuno* (syrup, lime rind); the doughnut-like Malaysian *kuih keria* of sago, rice, and

## SPICES OF SOUTHEAST ASIA

The range, subtlety, intensity, melding, and reinvention of flavors are made possible by the spice table shared by almost all of Southeast Asia. Among the spices are:

English	Malaysian	Indonesian	Filipino
garlic	<i>bawang putih</i>	<i>bawang-putih</i>	<i>bawang</i>
ginger	<i>haliya</i>	<i>acuga, jahe</i>	<i>luya</i>
galingale	<i>lengkuas</i>	<i>laos</i>	<i>langkawas</i>
chili	<i>chilli-api, chabai</i>	<i>lombok kecil</i>	<i>siling labuyo</i>
lemon grass	<i>serai</i>	<i>seri</i>	<i>tanglad</i>
Kaffir lime	<i>limau purut</i>	<i>jeruk purut</i>	
curry leaves	<i>daun kari</i>		
mint	<i>pohok</i>	<i>jaggat</i>	<i>yerba buena</i>
basil, holy	<i>sellaseh kemangi</i>	<i>kemangen</i>	<i>sulasi</i>
basil, sweet	<i>selaseh putih</i>	<i>selasih</i>	<i>balanoi</i>
coriander			
leaf cilantro	<i>ketumbar</i>	<i>katumber</i>	<i>wan soy</i>
coriander seed		<i>ketumbar</i>	<i>kulanthro</i>
turmeric		<i>kunyit</i>	<i>dilao</i>
star anise		<i>bunga lawang</i>	<i>sangke</i>
cloves		<i>cengkeh</i>	<i>clavo</i>
cinnamon		<i>kayu manis padang</i>	
cumin		<i>jintan putih</i>	<i>jinten</i>
pepper		<i>merica</i>	<i>paminta</i>
parsley	<i>shelwri</i>	<i>patraseli, seledri</i>	<i>parsli</i>
mustard seed	<i>biji savi</i>		<i>mustasa</i>
nutmeg		<i>pala</i>	
tamarind	<i>asam</i>	<i>asam Java</i>	<i>sampalok</i>

grated coconut; and the Indonesian *serikaya* (coconut custard) and *onde-onde* (small rice cakes rolled in grated coconut). The flavor of coconut at all its stages is savored throughout the region in recognizably compatible ways.

### Spices, Herbs, Relishes

Southeast Asian tables generally bear not only serving platters with dishes to be shared and individual plates or bowls but also little satellite dishes for dipping sauces, spices, chopped herbs, and relishes like shrimp paste and fish sauce. The meal may be prepared by great cooks or chefs, but each diner has the right and freedom to fine-tune the dish to his or her individual taste by dipping, pouring, mixing, and sprinkling and thus giving the dish its final grace.

Among the possibilities are the Indonesian *sambal* and *sambel*, hot and spicy relishes served with food. They feature red and green chilies, hot bird peppers, *terasi* (shrimp paste, which is made by salting and mashing tiny shrimp and allowing them to ferment), lemon, lime, soy sauce, shallots, chili powder, tamarind water, salted yel-

low beans, and more, depending on the dish they are to accompany. Others are *serundeng* (roasted grated coconut) and *goreng bawang* (crisp-fried onions) to sprinkle on particular dishes.

In the Philippines dipping sauces are called *sawsawan* and could be basic vinegar, soy sauce, *patis* (fish sauce, made by salting and fermenting small fish); *calamansi* (lime) juice; combined vinegar-soy or *patis-calamansi*; or enhanced with herbs and spices, such as crushed pepper-corns, ginger, garlic, chili peppers or seeds, coriander leaves, pork or crackling bits, and salted black beans. *Achara*, such as pickled papaya, mangoes, heart of palm, and chilies, are accompaniments as well. These make it possible to satisfy individual palates or to make each mouthful a different delight.

Parallels exist in Malaysian and Singaporean cooking, including prawn and shrimp pastes (*blacan terasi* and the mild Chinese liquid *bei-ko*); dried anchovy and fish sauce; the *rempah* spice mixture of *sambal* and *achar* (mangoes, mixed vegetables); and *goreng bawang* (crisp-fried onions). The famous Hainanese chicken rice of Malaysia

and Singapore may come with *sambal belacan* (red chilies, shrimp paste, limes) or at least three sauces, a fresh-made chili sauce, finely crushed ginger and oil, and soy sauce. *Nasi lemak*, the Nonya-Malay rice steamed in coconut milk, and its satellite dishes constitute the traditional festival dish for the twelfth day of a wedding. The accompaniments may include *sambal udang* (shrimp), *ikan kuning* (small fried fish), cucumber slices, and sliced red chilies.

The renowned Indonesian *rijsttafel* (rice table), although based on feasts of yore, has become largely a Dutch custom. Rice, the central dish, is surrounded with smaller dishes and relishes. Popular in Indonesia is a miniature *rijsttafel* called *nasi rames* with some seven side dishes, like *dendeng ragi* (beef and grated coconut), *sayur lodeh* (spicy vegetable stew), *rendang* (beef cooked in spices and coconut milk), *kering tempe* (crisp-fried *tempe*), *kelia ayam* (Sumatran chicken curry), *sambal bajak* (mixed spice relish), and *krupuk* (prawn crackers). Each spice-enhanced dish introduces a flavor or flavors to harmonize with the rest in a whole Asian experience.

The sauces include fish, oyster, *boisin*, chili, plum, black bean, yellow bean, chili bean, red bean, shrimp paste, sesame paste, and soybean; the cooking fats and oils are peanut, rape seed, coconut, sesame seed, palm, and chili; and the vinegars are rice, coconut, palm, sugar cane, and fruit. Combining all with the *sambals* and other made-up cooked or mixed combinations creates a repertoire of unnumbered possibilities, all Asian or Southeast Asian, a kaleidoscope of flavors and flavor makers.

### Chinese and Other Foreign Influences

All three countries have significant Chinese populations, which even make up a full third of the population in Malaysia, that may or may not have integrated successfully in the cities and villages. Consequently all have strong Chinese dietary strains in their cuisines. Even during racial conflicts—riots in Malaysia, wars and ghetto burning in the Philippines, discrimination and segregation in Indonesia—the foods melded and the Chinese presence became a matter of fact, even of pride.

Nonya cooking in Malaysia originated among Chinese immigrants who settled in Malacca in the fifteenth century. Daughters of well-to-do Nonya women were trained in household and cooking skills from early childhood. The cuisine uses chilies, shrimp paste, coconut milk, and aromatic roots and leaves as in the Malaysian and Indonesian traditions but also retains pork and noodles from its Chinese past.

The *popiah* or spring roll is often served in its separate pieces—the wrapper pancakes; fillings, possibly including eggs, sausages, bean curd, bean sprouts, prawns, cucumber sticks, spring onions, lettuce leaves, pork, crab meat, bamboo shoots, and water chestnuts; and sauces and relishes—on a round table at which each diner creates a spring roll to taste. The Nonya pork *sate* is a compromise between a Muslim prohibition and a Chinese

taste for pork. The resulting taste is Malay, with chilies, coconut milk, lemon grass, and coriander.

In the Philippines the first public eateries were Chinese establishments that served indigenized *comida China* (Chinese food) in restaurants called *carinderia*, a Spanish formulation from a native word *cari* or *kari*, cooked food. To accommodate the Spanish patrons, the food had Spanish names, such as *aletas de tiburón* (shark fins), *tortilla de cangrejo* (crab omelet), *camaron rebozado* (batter-coated shrimps).

Widely popular and variegated is the *lumpia*, a vegetable or pork spring roll in a thin flour wrapper, the local edition of the Malay *popiah*. The noodle dishes, generically called *pansit* from the Hokkien word for that which is quickly cooked, vary from region to region, indeed family to family, cook to cook. *Char kway teow* is the most popular Malay-Singaporean noodle, but in the Philippines the most popular is *pancit palabok*, noodles shaken in water or broth and covered with a sauce of shrimp, pork, vegetables, bean curd, and sometimes squid, oysters, crumbled crackling, and flaked smoked fish. In Indonesia it may be *mie jawa*, which includes *bakmie goreng* (fried noodles) or *bakmie godog* (noodle soup), egg noodles with beef or pork, shrimp or prawns, carrots, bean sprouts, shallots, candlenuts, and other seasonings.

Each country's colonial and social histories left deep imprints on its cuisine, the roots of many regional differences. The Spanish-Mexican and American colonial regimes, building on the indigenous and Chinese food already in place, shaped what is now known as Philippine cooking. Native to the soil are dishes like *sinigang*, a sour stew of meats, crustaceans, fish, or fowl soured with tamarind, *bilimbi*, green mango, or other sour fruits and leaves. Sour broths are cooling to the skin, especially in tropical weather. Indigenous too are fresh meat, fish, and fowl, steamed, simmered, boiled, or roasted, and vegetables cooked in coconut milk or steamed and flavored with shrimp paste or fish sauce.

Filipinos indigenized Chinese, Spanish-Mexican, and American dishes through the use of native ingredients and cooking by native cooks with homegrown taste buds. Among those dishes are Spanish stews (*cocido*, *puchero*) with eggplant or squash relishes; the Mexican tamale transformed from a corn snack wrapped in corn husks into a rice snack wrapped in a banana leaf; a Chinese porridge cooked in the Philippines with chicken and *kasubba* (a saffronlike spice) or including unhatched eggs; beef hamburgers with soy and chopped onions; and steaks marinated in soy sauce and lime juice before grilling. The foreign food has been accepted but adapted to local tastes.

The colonial experience gives Philippine dishes a European-American dimension, just as British colonization colored Malay-Singapore food and Dutch domination redefined Indonesian cooking. Of the latter two, however, the Dutch influence is the lightest, because the colonizers

## OTHER REGIONAL CUISINES

Most Southeast Asian societies have been in contact with each other and with other societies, such as India and China, for many centuries. Within Southeast Asia food serves as an ethnic and national marker, distinguishing one group from another. The region is characterized by a great diversity of cuisines that have been shaped by local geography, ecology, religion, and history. Despite the diversity, distinct commonalities exist. Ingredients like coconut milk, lemon grass, galingale, ginger, Asian basil, mint, fish sauce, and shrimp paste are used throughout the region. However, cooking techniques and the ways these ingredients are combined vary greatly and give each cuisine its distinctiveness.

### *Lao People's Democratic Republic*

Rice, especially the glutinous variety, is the staple for Lao meals. Other frequently used ingredients include fresh vegetables, freshwater fish, poultry, duck, pork, beef, or water buffalo. Lime juice, lemon, fresh coriander, and various fermented fish sauces give Lao food its characteristic flavor. *Pla daek*, a highly pungent fermented fish sauce, is often considered an ethnic marker. Additionally its heavy use throughout the country and the consumption of *laap* are indicators of the cultural and historical links with Northeast Thailand. Hot chilies, garlic, mint, ground peanuts, tamarind juice, ginger, and coconut milk are other seasonings that link Lao cuisine to others of the region. A soup, such as *kaeng nor mai* (bamboo shoot soup) or *kaeng het bot* (mushroom soup), is a common feature of Lao meals. One popular dish eaten by the Lao is *feu*, a noodle dish of Vietnamese origin. Another noodle dish, *klao poun*, is served cold with a variety of raw chopped vegetables and a flavored coconut milk sauce and is often a part of celebrations. *Or lam*, a regional dish in Luang Prabang, combines lemon

grass, sweet basil, dried buffalo meat and skin, chilies, and eggplant.

### *Myanmar (Burma)*

Myanmar is a diamond-shaped country bounded by China, Laos, and Thailand in the east, by Bangladesh and India in the north, and by the Indian Ocean in the west and south. The landscape is mountainous, and only about one-sixth of the country is considered arable. Of the arable land, approximately one-tenth is irrigated, mostly for rice agriculture. The cuisine is considered a blend of Burman, Mon, Indian, and Chinese influences, and hot and spicy dishes particularly show the influence of Indian and other Southeast Asian cuisines. Rice, the core of most meals, is often eaten with curries of fish, chicken, or prawns, and noodles and vegetables are common local ingredients. Taste combinations of onion, ginger root, garlic, turmeric, and chili pepper give the cuisine its distinctive flavor. The curries in Myanmar are the mildest in Southeast Asia, but the heat level can be intensified by adding *balachaung*, a condiment made from chilies, tamarind paste, and dried shrimp, or *ngapi kyaw*, a hot and pungent shrimp paste fried in oil with garlic and onions.

### *Kampuchea (Cambodia)*

Kampuchea shares borders in the north with Laos and Thailand, in the east with Vietnam, and in the southwest with the Gulf of Thailand. Khmer is Cambodia's official language, and Theravada Buddhism is the dominant religion. Fish, rice, coriander, and lemon grass are common dish ingredients. A Cambodian meal almost always includes a soup, which is eaten with the other dishes. As elsewhere in Southeast Asia, freshwater fish is a mainstay. Some dishes reflect the influence of French cooking, as does the use of bread.

were not too interested in changing the native culture of the colonized. However, Spanish colonization of the Philippines, which meant Christianization as well, was much more deeply engaged in culture change, as was American colonization, which made its impact through language and education. In Malaysia, the Indians, Chinese, immigrant elites from East and Southeast Asia, and Europeans influenced food more strongly than did the British.

### **Southeast Asian Cuisine in the Twenty-first Century**

Although it is logical and true to speak of the individual sister cuisines of Southeast Asia, they are variations on

regional themes. A common repertoire of spices, rice, coconuts, vegetables, fish, fowl, and animals exists. The lands and waters and the trade and interaction have made that inevitable. Thus the cuisines have compatible attitudes, common practices, and recognizable similarities. However, the differences wrought by history, especially the colonial experiences and the strategies of survival; social forces, including war, peace, trade, and population; and the countries' cultures, that is, the way people think, work, survive, and express themselves, have resulted in the kaleidoscope of tastes and dishes in Southeast Asia.

The Indonesian *pisang goreng*, bananas mashed with sugar and flour, and the Philippine *linupak*, green bananas

mashed with sugar and coconut, and *pinasugbu*, green banana slices dipped in molasses syrup, are variations on a theme. The Nonya pancake, a teatime snack filled with palm sugar and served with chocolate sauce, and the Philippine *piaya*, a flat cake filled with brown sugar and sprinkled with sesame seeds, are also variations. The similarities are clear, but regional circumstances gave them particular characteristics. On warm afternoons Indonesians enjoy *es cendol*, short strands of two kinds of flour sieved, flavored, and served with sugar syrup, coconut milk, and ice crushed or cubed. Malaysians have *bubor cha-cha* with yam and sweet potato cubes, tapioca, sweet coconut milk, and ice shavings. Filipinos serve instead *halo-halo* (literally mix-mix) with palm fruit, gelatin cubes, banana slices, sweetened coconut strands, milk, and crushed ice. The mixtures are analogous because the weather and the habits of refreshment are too.

The famous dishes of each cuisine may have tastes familiar and acceptable to the whole region, but they are different and make a rich repertoire. In Malaysia celebrations may include chili crab, *satays*, a steamboat, the Nonya *sambal sotong* (squid) or *sambal udang* (prawns), *bakwan kepiting* (a Nonya must for Lunar New Year's and birthdays), the Hokkien-Nonya *ngoh hiang* (five-spice rolls with prawns, pork, and crab meat), *rebong masak lemak* (chicken and bamboo shoots), *sambal kim chiam* (a salad of banana buds), Indian-based vindaloo (chicken or duck), and clay pot dishes and soups of Chinese origin. Malaysians and Singaporeans consider many other dishes connected to their multicultural family feasts and traditions.

Philippine feasting often features colonial food, such as Spanish stews (*cocido*, *puchero*) with sausages (chorizo, *morcilla*); sugar-glazed Christmas hams (*jamon en dulce*); stuffed turkeys and capons (*pavo embuchado*, *capon rellenado*); and American salads, pies, and cakes, once considered elite and thus appropriate for celebrations. To these time and custom have added specialties of Chinese origin, especially noodles, roast duck, roast pig, steamed fish chosen live from a tank, bird's nest and shark fin soups, and delicate dumplings and buns. The indigenous rice cakes, rolls, and desserts; stews like *kari-kari* (oxtail); and special dishes like *lechon* (tamarind leaf- or lemon grass-stuffed suckling pig skewered and roasted on an open fire) are the local contribution to a cuisine that combines the indigenous, the indigenized, and even the imported.

Indonesia, with so many regional traditions, has one of the richest cuisines, and the Western world, which has sent more scholars to Indonesia than to any other Southeast Asian country, has explored it. The names sound rare and enticing, like the famous beef *rendang*; the hearty *gado-gado* salad of cooked vegetables; the different *gulai* (vegetables like *pako*, fiddlehead fern) cooked in coconut milk; fish and fish cakes; *sates* of lamb, beef, and chicken; *bebek dengan bumbu betutu* (duck breasts in Balinese spices); *bubur ayam* (rice porridge with spicy chicken soup); and sweets like *rujak* (a spiced fruit salad), *marabak kubang* (Sumatran stuffed pancakes), and *lapis legit* (spiced

layered cake). Southeast Asian ingredients, spices, cooking methods, dishes traditional and new, meal patterns, and border-crossing food and foodways remind readers of cookbooks, menus, and travel, ethnographic, and anthropological accounts that the words are the merest keys to cultures deep and rich, starting points for meals, for cultural interactions, and for rich conversations with national identities, time, and traditions.

#### THAILAND

Thailand is situated in the heart of mainland Southeast Asia. Located between latitudes 5° and 21° north and longitudes 97° to 106° east, it borders the Lao People's Democratic Republic (Lao PDR) and Myanmar (formerly Burma) to the north, Cambodia to the east, Myanmar to the west, and Malaysia to the south. Tropical temperature and rainfall patterns predominate throughout much of the country and influence its culinary traditions. Thai-

land, once called Siam, is distinguished from most other Southeast Asian countries by the fact that it has not ever been ruled by a European power. The monarch is a member of the Chakri dynasty, which has led the kingdom since 1782. Much of the Thai cuisine evolved in the central region during the Sukhothai period (1238–1350 B.C.E.). The rise of Ayutthaya in the fourteenth century brought an increase in trade, and outside influences became more pronounced. China, India, Indonesia, and Cambodia exerted strong influences, as did some European countries. After the fifteenth century domesticates from the Americas, such as the chili pepper and the tomato, were introduced. The complex of seasonings and dishes regarded as Thai cuisine was probably well established by the 1800s.

### Staples, Specialties, and Etiquette

Rice and fish were first used as metaphors for prosperity and security in the inscription from King Ramkhamhaeng (1283 C.E.): “In the water there are fish, in the paddies there is rice” (*nai nam mee pla—nai na mee khao*). Rice, fish, and local fruits and vegetables form the centerpiece of Thai cuisine. Considerable evidence suggests that the domestication of wild rice occurred in the Yangtze Valley in China and later spread to Thailand and other areas in Southeast Asia. Rice is more than just a culinary staple. Rice agriculture is the primary farming activity nationwide, an integral way of life often portrayed in songs, poems, novels, and films. Rice is so central in the Thai diet that the most common term for “to eat” is “*kin khao*,” literally “eat rice,” and a common greeting is “*Kin khao laew rêu yang?*” literally “Have you eaten rice yet?” Regional distinctions exist in the type of rice consumed. Sticky or glutinous rice (*khâaw niaw*) is consumed widely in the north and the northeast, and plain white rice (*khâaw jâo*), especially jasmine rice, is popular in the central and southern regions (see “Thai Regional Cuisine” below). Glutinous or sticky rice is a variety (*Oryza sativa*) that requires a shorter growing season and contains a large amount of amylopectin starch. The high propor-

tion of amylopectin causes the kernels to disintegrate when boiled. Consequently glutinous rice is usually soaked and then steamed in a container above the water.

Eating in Thailand is usually done in a social context rather than alone. In Thai the word for “meal” is “*meu*,” and meals usually consist of rice accompanied by various side dishes that are not eaten in any specific order. Frequently meals include a soup, a curry (*kaeng*), a salad, a steamed or fried dish, and at least one dipping sauce, such as fish sauce *nam pla* or one of the various forms of the hotter *nam prik*. Dessert usually consists of fruits, although various sweets called *kanome*, which are sometimes eaten as snacks, can also be served at a meal. Specific foods are seldom limited to certain times of the day, and distinctive breakfast, lunch, or dinner dishes do not exist. Some Thai food is eaten with the fingers, especially in certain regions of the country or specific foods such as sticky rice. The use of a fork and spoon predominates in urban areas, where the fork is used to push

food onto the spoon rather than to bring food to the mouth. Knives are not commonly used because food is usually cut into small pieces before it is cooked.

Traditionally some distinction is made between food eaten by royalty (*abaaan chow wang*) and village food (*aaban chow baan*). The primary difference lies not so much in the ingredients as in the use of serving dishes, in the variety and number of side dishes, and in the presentation style as food is transformed by carving, shaping, or decorating to change its appearance. In addition to an artistic presentation, palace food has often required many hours of preparation. Traditional palace food is served in Bangkok at restaurants specializing in this type of cuisine. Some royal desserts such as *foi thong* (golden threads), a dessert made from egg yolks and sugar, and *luk choob*, small mung bean paste sweets, similar to marzipan, shaped into small replicas of various fruits, colored with vegetable dyes, and glazed in the gelatin-like agar-agar. These sweets also can be obtained in many large grocery stores and from some street vendors.

A twentieth-century development, especially in the urban areas, was the rapid rise in Thai street food. Sometimes considered a culinary form in its own right, street food is characterized by rapid preparation methods and includes a wide variety of categories. Snacks, such as sliced fruits or sweets, are common, as are noodle dishes and main dishes. Usually each vendor concentrates on one of these categories of food. Sidewalk food vendors are regulated by official authorities in each city. This form of culinary activity clearly fills an important niche in the cosmopolitan Thai lifestyle.

### The Tastes and Flavors of Thai Food

The consumption of meals is guided by the qualities of taste, smell, and texture. Often these are the same qualities that guide health-promoting behavior. Foods are classified and categorized in a variety of ways. The ingredients selected for cooking frequently have medicinal properties. Penny Van Esterik (1988, p. 753) notes that the taste relationship is so close to concepts of health that the head teacher of the Traditional Medical College identified medicine (*ya*) as “anything which can be eaten to improve one’s health.” The basic taste qualities overlap with the medicinal tastes of traditional Thai medicine, which is related to the Indian Ayurvedic system. These taste contrasts guide the combination of ingredients or the combination of dishes with rice. The tastes are primarily derived from local plants, resins, oils, roots, insects, and algae, many of which are gathered wild from forests, ponds, and rice paddies.

Flavoring is a defining characteristic of Thai cuisine that imparts regional or ethnic identification, a sense of familiarity, and a sense of tradition. Most Thais speak of five important tastes as the hallmarks of Thai food, sweet, sour, salty, bitter, and hot-spicy. The ideal meal is often designed to include these tastes, and sometimes several of the tastes are subtly combined in an individual dish. Despite regional differences, much of Thai food is characterized by a combination of *naam plaa* (predominantly in the central, northern, and southern regions) or *plaa daek* (in the northeast), lemongrass, ginger, galingale, Thai basil, garlic, and chili peppers. A wide variety of chili peppers is used, different types imparting distinctive

## REGIONAL CUISINES OF THAILAND

Thailand is divided into four regions, the North, Northeast, Central, and South, which vary in geography, natural resources, culture, and history of contact with outer societies. Consequently each is characterized by its own foods and style of eating, although the increase in communication and extensive internal migration has been accompanied by the movement of regional dishes into different areas within the country.

### ***The North***

Northern Thailand, site of the early Thai city-states Lanna, Chiang Mai, and Chian Saen, borders Myanmar, Laos (Lao PDR), and China. Consequently the food of the North is an amalgamation of cuisine from these areas. The importance of sticky rice in the North is a reflection of dietary influences from Laos. The use of pork, tamarind, and turmeric belies the influence of Myanmar, as does the regional specialty *kaeng hang le* (a pork curry). Mild-hot, salty, and sour tastes predominate, and local dishes contain bitter acacia leaf, eggplants known for their bitterness, sour tamarind juice, and pickled bamboo shoots. A traditional form of a meal in this region is the *khantok* (*khan* means bowl, *tok* means low, round table), during which diners sit on the floor around a low table.

### ***The Central Region***

The Central region dominates the nation politically and economically. Hot, salty, sweet, and sour tastes predominate there. The cuisine of Central Thailand is characterized by curries made with coconut milk and spices, such as *kaeng phèt* (red curry) and *kaeng khīaw wǎan* (green curry). Stir-frying with basil and curry paste (*phàt phèt*) is also common, as are the well-known soups *tôm yam gông* (spicy shrimp soup) and *tôm khà gài* (chicken coconut soup). *Yam*, the hot and tangy salad, is most popular served with squid or barbecued beef or pork.

The Chinese community has had a large influence on Central Thailand as can be seen in *Kūaytǎow*, noodle dishes, and the clear bitter soups made with green squash, bitter gourd, and ground pork. The eastern seaboard region is increasingly gaining attention as a separate region characterized by its reliance on seafood and distinctive fruits.

### ***The Northeast (Isan)***

Isan is characterized by hot, spicy, salty, and sour tastes. Food in this region reflects its relationship and similarity to neighboring Lao PDR. Some of the earliest archaeological sites in Asia with evidence of agriculture, pottery, and bronze work are located in the Northeast. Consumption of glutinous rice is a distinctive characteristic of Isan. The food is frequently flavored with *pla daek*, a fermented fish sauce. One special dish from the region is *laab* or *kôy*. This dish is a blend of minced meat, fish sauce, herbs such as cilantro and mint, scallions, lime juice, ground roasted sticky rice, and chilies either fresh or in powdered form. *Sôm tam*, a spicy green papaya salad, and grilled chicken are also characteristic of Isan.

### ***The South***

South of Bangkok the country rapidly narrows to a strip of land connecting Thailand with the Malay Peninsula. Culturally the South is distinctive, with a large Muslim and Chinese population. Hence much of the food of the South combines Thai, Malay, and Chinese elements, and the prevailing tastes are hot, spicy, salty, and sour. Curries in the Indian style, such as Massaman curry, are the predominant features of southern meals. Additionally influences from the Middle East and Pakistan are evident, for example in *roti* (flat Indian bread). The use of a pungent, flat bean, *sato* (*Parkia speciosa*), which imbues a bitter taste is also favored in this region.

tastes, colors, and levels of hotness, such as the small and extremely hot *prik ki nu*. In addition mint, coriander, lime, and kaffir lime leaves (*Citrus hystrix* DC.) are also frequently used.

### **Food in Thai Celebrations, Rituals, and Religion**

Food plays an important role in the personal, social, and religious aspects of Thai life. Most Thais are Buddhists, and the daily offering of food to monks, called *tham boon tak bàat*, is one of the most important Buddhist acts. Every day throughout the country, in urban and rural communities, Thai Buddhist monks receive their daily food during a practice known as *bintábàat*. Walking through the streets and paths in the early morning, the

monks are met by people offering food. Food is also offered at numerous religious shrines and is an important part of most Thai Buddhist ceremonies. Houses, office buildings, hotels, and rice fields have a spirit (*phii*) house (*san pra poom*), where daily offerings are placed. The spirit houses, originating from past Brahman influences, may be elaborate and look like small temples or may be modestly constructed of plain wood or concrete. Thais give offerings to feed the spirits occupying the spirit house who protect the place from harm. As in secular life, rice has a central role in Thai spiritual life. The most common type of offering at spirit shrines is a small amount of rice, however, other food, such as fruits or sweets, may also be provided.

Thai candies are often made of exotic tropical ingredients. These confections were displayed in a shop in Bangkok. © DAVE BARTRUFF/CORBIS.

Buddhist monks perform many different ceremonies in which food offerings are integral. These include funeral rites, weddings, house consecrations, and inductions of new monks. Sweet offerings predominate at engagement and wedding ceremonies. The names of such sweets often signify a special aspect of the occasion. For example, *kanome* (sweet) *thong* (gold) *ake* (best) signifies bestowing wealth to the couple. The preparation and offering of food for religious ceremonies and rituals bestows merit on the person who provides the food. In preparing and giving ritual food individuals gain merit, and food is integrated into the spiritual and ceremonial fabric of Thai life.

## VIETNAM

The Vietnamese cuisine has been described as one of the most colorful and diverse in the world. The country's geography, climate, and history all play influential roles in creating its culinary range. The Vietnamese often describe their country as resembling a shoulder pole laden with two rice baskets. In fact, both the northern Red River delta and the southern Mekong River delta are rice-producing regions. The long coastline, rivers, and tributaries have ensured the place of seafood throughout the country, while the distinctive climates and cultures found in the North, Middle, and South, along with Vietnam's mountain-lowland ecologies have produced regional variation in the diet. Finally, Vietnam's relations with China (which controlled it for a thousand years, beginning in 111 B.C.E.), its Southeast Asian neighbors, India, France, and the United States have affected what the Vietnamese have chosen to eat, or been forced to eat, throughout their history.

### Food Beliefs

**Philosophy.** Taoism, Buddhism, and Confucianism play an important role in Vietnamese food beliefs, but rural pragmatics are part of even the most cosmopolitan individual's belief system. According to Vietnamese from the countryside, there are two important qualities in food: quantity and taste. The elderly and guests, including spiritual ones, also require more prestigious food than is commonly eaten by everyone else. While the majority of Vietnamese profess a belief in Buddhism, relatively few adhere to Buddhist dietary prohibitions against meat and alcohol. The foods preferred in ancestor worship, and usually placed on an altar with incense and wine, were chicken and rice. These are the same foods that are served to company when possible. Pork is usually served at feasts.

**Science.** The Vietnamese regard two distinct health systems as scientific: Western medicine as practiced by the French and Western-trained physicians, and *thuoc bac*, literally "northern medicine," but colloquially "Chinese medicine." According to most sources, *thuoc bac* incorporates Chinese and Indian (Ayurvedic) traditions, and was possibly influenced by the humoral pathology of the classical Greek physician Galen (129–199 C.E.). In this frame of reference, health reflects a balance of two basic elements, *am* (the Chinese *yin*)—often translated as "cold"—and *duong* (Chinese, *yang*), or "hot." Ill health is the disequilibrium of these forces brought about by incorporating too much *am* or *duong* in the body. Foods share these designations, and can either upset the balance through deficit or overindulgence, or be used therapeutically.

A Vietnamese interpretation of the life cycle is that following childbirth, the mother and infant are both cold. As the infant develops, he or she becomes warmer. This warmth peaks in adolescence (teenagers are the hottest), and then the adult begins to cool down, maintaining neu-

trality (the desired state) through maturity. The body becomes cool again in old age. Foods are recommended according to these life stages. Immediately following birth, for example, the mother is given hot foods and treatments (which are shared with the infant through breast milk). Infants and young children, while frequently troubled by cold illnesses such as diarrhea and stomachache, are naturally warm, with a tendency toward rashes, fevers, and constipation. Adults can acquire hot or cold illnesses that need to be counterbalanced by treatments and diet. The elderly tend to be cold, and frequently require therapeutic warming. Cigarette smoking used to be advocated for the elderly (the Vietnamese term for tobacco is *thuoc la*, or "medicinal leaves").

As is true in all humoral systems, the food's temperature has little to do with its qualities of *am* and *duong*, boiled water being the exception (water boiled, then cooled, is warming, whereas cool water is cold. Ice is hot!). Most green vegetables are considered cooling; fatty foods such as meat, sugary foods, and red or orange fruits

(such as papaya, mango, or watermelon) are considered heating.

### A Vietnamese Meal

The majority of Vietnamese cuisine is relatively simple, relying on fresh fish, vegetables, fruit, and steamed white rice. Rice is so important in the diet that the words used to enquire if someone has eaten are *an com roi*, or, “eaten rice yet?” Fish sauce (*nuoc mam*) made from fermented anchovies is used much like soy sauce in Chinese cuisine. Few Vietnamese dishes do not include a drop or two, and Vietnamese have often subsisted on little more than fish sauce on rice, when they were lucky enough to have rice.

A typical Vietnamese meal requires rice, soup (with greens), a fried dish of fish, meat, or vegetables, and fish sauce on the side for additional flavoring. This meal would be prepared in sufficient quantity that it would be consumed for lunch and dinner. The primary factors normally taken into consideration when preparing a meal include the number of people needing to eat, their ages and associated needs (according to the theory of *am* and *duong*), taste preferences, cost of the foods, and ease of preparation.

The Vietnamese like to eat three meals a day, with breakfast often consisting of a thick rice soup (*chau*) like the Chinese congee, bread products, or foods identical to those consumed at other times of the day. The Vietnamese appreciate coffee, preferring a dense, slow-dripped preparation mixed with sweetened, condensed milk. Noodles (with or without soup); fresh or dried fruits; salted, roasted seeds; dried squid; and just about any salty, chewy food makes up the snack world.

Tea, various infusions of seeds or herbs (particularly lotus roots or seeds), soft drinks, and beer (usually drunk with ice) are consumed throughout the country, with beer (including the artisanal variety *bia boi*) edging out the other drinks in terms of popularity among men in the South. Everyone drinks water, preferably rainwater col-

lected in large earthenware jars. Water is also consumed from local ponds and streams, although much of it carries a heavy parasitic load.

### Holiday Food

While rice is the “pearl of heaven,” plain cooked rice is not a prestige food. Celebratory foods gain their prestige because of the limited availability of their ingredients or the difficulty of their preparation. Often rice flour cooked into sheets is the basis for delicate preparations, or pounded rice is used to make sumptuous cakes filled with bean paste, pork, or other delicacies. The principal holiday is Tet, the Vietnamese lunar New Year; it usually occurs in February. A child’s first birthday (at which time he or she is considered to be two years old) is celebrated to mark survival of the perilous first year of life, when many infants die. Foods common in Vietnamese restaurants in the United States, such as *cha gio*, which require a lot of preparation, are normally reserved for Tet and first-year celebrations. Coca-Cola (seemingly the only U.S. contribution to Vietnamese cuisine) or beer are the accompanying beverages of choice. Urban birthday meals include colored rice cakes and purchased French layer cake with frosting. And the urban way of celebrating a wedding is to take the entire extended family and other guests to a Chinese restaurant. There eight to ten courses of meat, fish, and poultry, and very little rice, are served.

### Regional Variation

The North of Vietnam, with its colder climate and proximity to China, is the home of *pho*, the famous beef broth with noodles and thin slices of meat. Accompanying herbs such as mint, basil, green onions, and bean sprouts grow in the northern climate. Grilled meat and stir-frying are more common food-preparation methods here. There are fewer vegetables and fruits available.

Central Vietnam has an important historical heritage that adds chili peppers, other spices and characteristic presentation style to the cuisine. A “kingly” table consisted of many small dishes instead of a common bowl, which is the “common” (and ubiquitous) way to serve the family. The cuisine of Hue, the ancient capital, is also more seasonal than in the North or South, reflecting not only the availability of vegetables, fruits, fowl, and seafood, but the humoral qualities of people at this time of year as well as the food. The sweet pudding *chè*, usually made with beans or lotus seeds, hails from this region.

The South’s hot and humid climate produces a year-round, changing supply of vegetables, fruits, and livestock. The South is also the social pressure cooker of Vietnam, with a fourteenth-century origin as an Indianized Khmer region, followed by Vietnamese sovereignty in the eighteenth century. The French occupied the region from the nineteenth through the middle of the twentieth century, when the Vietnamese took power again. Dishes such as *bánh xèo* have been described as a Vietnamese crepe, or an Indian *dhosa*, depending on how far

Women taking breakfast in front of their house in Vietnam. Socializing with neighbors is an important feature of this early morning meal. © JOHN R. JONES; PAPILIO/CORBIS

Laotian serving basket for sticky rice. Laos, ca. 1975. Reed grass on wooden base. This server holds enough sticky rice for one person. The rice is eaten with the fingers instead of using chopsticks. These baskets are also made in regions of Vietnam and Thailand that border on Laos. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

back in time the form is thought to have originated. Curries, asparagus, avocado, little white potatoes, French bread, and mayonnaise all make their way to the table in Ho Chi Minh City (formerly Saigon). Many dishes combine fish with vegetables or sour fruits, such as tamarind or pineapple. And “pâté” can refer to anything from a mixture of ground pork used to fill the famous Vietnamese spring roll (*cha gio*) to a shrimp paste spread on French bread.

The hill tribes of Vietnam, such as the Hmong, are fewer in number today due to their collaboration with South Vietnamese and U.S. forces during the Vietnam War; many were evacuated to the United States at the end of the war. Tribal groups, however, respect national borders less than altitude, and move somewhat freely between Thailand, Laos, and Vietnam. They practice slash-and-burn agriculture, raise and consume pigs, and prefer glutinous (sticky) rice, which can be eaten with the fingers, to the long-grain variety preferred by lowlanders, which is always consumed in a small bowl with chopsticks. They trade the products of poppies (seeds; opium)

and their renowned silverwork and embroidery for food products from the lowland areas.

It is impossible to not mention that millions of Vietnamese, highland and lowland alike, have known starvation throughout their history. Vietnam’s struggle with the Chinese, with the French, with Japanese occupiers at the end of World War II, and with the Americans have resulted for varying periods in outright food shortages or broken distribution systems. Ho Chi Minh was able to gain support for his version of communism in part because of inequalities in the rice trade and widespread hunger in the North. The colonial system introduced many French delicacies to urbanites, but the rural poor subsisted on what they could grow on rented plots or fish from the irrigation canals of the plantations on which they worked for minimal wages.

Global economic downturns aside, Vietnam in the early twenty-first century appears to be well on the way to a stable economy. North-South differences in cuisine are still distinctive, even though the country has been unified since 1977. The hotel restaurant training school in Hanoi is bustling with noontime clients daily, with avocados and French onion soup prominent on the menu. Tens of thousands of Vietnamese now live outside the country, with most settled in the United States, Australia, France, and Canada. Expatriate Vietnamese have brought their cuisine to these countries, where it continues to evolve, incorporating a few local items into the rich Vietnamese culinary inventory.

**SOY.** The symbiosis between the soy plant and Rhizobium bacteria in the soil underlies the soybean's success as a major source of protein for human populations in Asia and domesticated animals in many countries, as well as an important renewer of land fertility in traditional agriculture. Rhizobium bacteria enter the root hairs of the soy plant (and those of other legumes), helping to form nodules where they feed on the plant's carbon supply. In exchange, the bacteria convert atmospheric nitrogen gas in the soil to ammonium, rendering the nitrogen accessible to the soy plant for use in protein synthesis. The resulting soybean is high in amino acids in ratios that make it, when compared to other known plant sources of protein, strikingly "complete" as a human food. Additional benefits are imparted when legumes such as soy decay. Bioavailable nitrogen is released into the soil, becoming accessible to other plants that lack symbiotic relationships with nitrogen fixing bacteria. Soy and other legumes have therefore played a crucial role in crop-rotation farming, contributing to the growth of other crops and pasturelands. Soybeans are also high in oil content, and in the latter twentieth century became the world's top source of edible oil.

### Physical Characteristics of the Soy Plant

Erect and bushy, the soybean plant can grow to over six feet high. It has ovate leaflets in groups of three; white, purple, or pinkish self-fertilizing flowers; and one to five beans in each pod. As with other legumes, at maturity the pod bursts open on both sides to expose the beans. Beans range in size from 1 to 3.5 centimeters or more and can be yellow, green, brown, black, reddish, or bicolored; their variations offer mute testimony to generations of selective breeding. The beans are 15 to 20 percent oil, and 35 to 45 percent protein, depending on the variety and farming conditions.

Timing of the soy plant's maturation is highly sensitive to day length; each variety requires a specific span of darkness to induce flowering. Known as photoperiodicity, this phenomenon makes the optimal choices of varieties different for each latitude where soybeans are grown. Soy's extreme photoperiodicity, along with its vulnerability to frost, probably slowed the early spread of its cultivation in China. Under the right conditions for any given variety, however, soy is a reliable crop that tolerates poorer soils. For this reason, in ancient China it was deemed invaluable as protection against famine should other crops fail.

Soy also has nutritional virtues beyond its protein and oil. Although their nutritional value varies with the

growing conditions, in general the beans provide modest levels of vitamin A, vitamin E, thiamine, riboflavin, other B-complex vitamins, potassium, phosphorus, magnesium, calcium, and iron.

### Origins, Domestication, and Diffusion of Soy

The soybean, *Glycine max*, is a cultigen that apparently does not exist in the wild. Botanists believe its wild ancestor was *Glycine ussuriensis*, a vine native to Taiwan, Korea, Japan, the north-central and far northern areas of eastern China, and adjacent areas of Russia. Chinese legend has it that sometime between about 2800 and 2400 B.C.E., the Emperor Shen Nung, father of Chinese agriculture, first extolled the virtues of the soybean in writing. Contemporary sinologists believe, however, that Shen Nung's famous treatise—indeed, Shen Nung himself—are the inventions of a much later era. As Theodore Hymowitz details in his "On the Domestication of the Soybean," botanical, archaeological, and linguistic research suggest instead that the trial-and-error process of domesticating soy began during the Shang Dynasty (circa 1600 B.C.E.–1027 B.C.E.), and that *Glycine max* did not emerge as a successful domesticate until the eleventh century B.C.E., probably in the north-central section of eastern China.

Soy cultivation gradually spread; evidence suggests that by the first century C.E., it had reached northern Manchuria, Korea, central and south China, and northern Vietnam. The expansion and contraction of Chinese dynasties was probably instrumental in this spread, as were the activities of Buddhist missionaries, who encouraged soybean cultivation as an expression of their vegetarianism. Buddhists were also the likely agents of early soy cultivation in Japan, beginning around the sixth century C.E. The emigration of ethnic Thais from China during the seventh century C.E. spread soy agriculture to present-day Thailand; traffic along the Silk Road brought soy to the northern Indian subcontinent in the eleventh and twelfth centuries. Between the first century C.E. and the sixteenth, soy was also introduced to Indonesia, the Philippines, Malaysia, Burma, and Nepal.

In the twentieth century, the bulk of the world's soybean production shifted to the New World. Although soy was first cultivated in what is now the United States in 1765, it was not a leading U.S. crop until World War II. In the 1970s, South American nations also began expanding soy production. Today the primary growers are the United States, which produces about half the world's supply, Brazil, China, and Argentina.

### Developments in Soy Agriculture—Demand and Supply

**Demand.** Unless adequately processed, mature soybeans are difficult for humans to digest and contain antinutritive components. In early centuries, the Chinese considered soybeans important yet undesirable—poor man's food. But once they learned to make palatable and

nutritious processed soy products, beginning around the third century B.C.E., demand for soy increased. For centuries, however, the demand for soybeans in Asia had little influence elsewhere.

In the 1920s, soy oil was used in the United States for industrial purposes; by the late 1930s, research was improving its flavor for American palates. At that time, the oil was lucrative; the protein meal was a cheap by-product fed to animals. During World War II, with imports of foreign vegetable oils cut off, the U.S. government promoted a huge expansion of soybean harvesting. Although the oil commanded a higher price per pound, the enormous surplus of meal came to provide more overall profits as Americans—and gradually people in developed countries worldwide—began to eat far more meat than ever before.

Today some 95 percent of the soy meal used in the United States is consumed by meat-, egg- or dairy-producing animals. This pattern is repeated in numerous countries that import soy from the United States, such as Mexico and in Europe. Even in Japan, where soy protein is an integral part of human diets, more soy is used for animal feed than for human consumption.

**Supply.** Early in the twentieth century, the development of tractors and combines made profitable, large-scale soy farming possible in America. A system was developed for storing soybeans at the right conditions of temperature and moisture at processing plants and in giant grain elevators; the Mississippi River became a crucial artery for soy exports. Soy agriculture worldwide has benefited as well from research on managing pests and diseases, including programs for breeding pest-resistant varieties.

Breeding programs have also been critical to the success of soy farming in varying growing conditions and for various desired traits (for example, higher oil or protein content), beginning with Asian farmers' patient work over centuries. More recently, plant breeders developed varieties tolerant of equatorial latitudes, making cultivation of soy in tropical Brazil profitable.

Since 1996, soy genetically modified with a gene from bacteria has become popular among farmers in the United States and Argentina. This soy is engineered to tolerate the Monsanto company's herbicide, Roundup, enabling farmers to use the herbicide easily without killing their crop. In the year 2000, over 50 percent of soy acreage in the United States was planted with "Roundup Ready" (RR) soy; it is currently the most grown genetically modified (GM) crop in the world.

RR soy is present in minute quantities in a wide array of American processed foods. Nutritionist critics worry that it could provoke allergic reactions in sensitive individuals, although to date there is virtually no scientific evidence of such a problem. Environmentalists fear that the gene for resistance to Roundup could "jump" to other plants, creating superweeds. Although some scien-

tific evidence may support this concern, so far the problem has not materialized. Prestigious organizations such as the National Academy of Sciences have called for more government supervision of GM crops, however. There is, as well, a small but growing market for organic, non-GM soy used to make foods high in soy protein ("soyfoods"), both in the United States and in other developed nations.

### Modern Trade in Soy

In the early twentieth century, Europe and the United States imported Manchurian soybeans for oil. Beginning in 1930, however, tariffs protected the American soybean industry. Gradually, soybeans (whole, as meal, and as oil) became the America's primary agricultural export; currently almost half the U.S. crop is sent abroad. This trade is controlled by a handful of powerful international grain companies. The expansion of U.S. (and Argentine) soy exports for human consumption is, however, hampered by concern in Europe (and to a lesser extent Japan) over the safety of GM soy; Brazilian soy is often preferred in these markets. Meanwhile, U.S. soy is making major inroads in the Chinese market, particularly with the entry of China into the World Trade Organization.

### Processing Soy for Different Cuisines

**Processing whole soy.** In Asia, soy is prepared in many forms. Immature soybeans simmered in their pods (Japanese *edamame*) and sprouts from soybeans germinated in darkness are two vegetable uses. Soymilk is made by adding water to the beans, grinding and heating them, and filtering out the "milk"; in recent decades it has become quite popular in parts of Asia as a noncarbonated soft drink. Yuba is the thin protein film that forms on the surface of hot soymilk; skimmed off and sold in sheets, it is a delicacy in China and Japan. Tofu is made by curdling hot soymilk with a salt or acid coagulant and then pressing the whey out of the curd. Subsequent processing

Farm workers grading soybeans by hand in Vietnam, 1997. © TIM PAGE/CORBIS.

of tofu can include freezing, freeze-drying, deep-frying, or grilling, yielding different textures, flavors, and nutrient profiles. Okara is the pulp that remains after filtration of soymilk. It can be pickled or cooked with meat in stews. Soynuts are whole roasted soybeans consumed as a snack; when ground into a powder, they are used in pastry-making (China, Japan) or eaten with rice (Japan, Indonesia).

Asian societies have also developed many fermented soy products, including fermented tofu (sufu, or “Chinese cheese”) and fermented okara. Fermentation increases soy’s digestibility, preserves soy for long periods, and, crucially, provides flavoring to stimulate the appetite. Many fermentation processes use *Aspergillus* fungi, salt-loving yeasts, and lactic acid bacteria. Products include soy paste fermented with or without wheat, barley, or rice (for example, jiang in China; red, white, yellow, or brown miso in Japan); soy sauce, which is made from soy and wheat (either by fermentation or chemically); fermented soy nuggets (“salted black beans”); tempeh, an Indonesian soy cake fermented with *Rhizopus* mold, served as a main dish, and—when prepared in the traditional manner—often high in vitamin B<sub>12</sub> from bacteria exposure during processing; and natto, a sweet, slippery, bacteria-fermented Japanese soybean dish served with soy sauce, mustard, and rice for breakfast or dinner.

In North America there is a small but growing market for soy products. Among those made from whole soybeans, the popularity of flavored soymilks and tofu is complemented by the marketing to vegetarians and health-conscious consumers of Western-style soyfoods such as soy yogurt, frozen soy desserts, and (unfermented) imitation cheese made from soy. In addition, full-fat soy flour is widely used commercially to bleach wheat flour and to condition doughs for Western-style breads.

**Processing soy oil.** Oil is extracted from soybeans either via chemical solvents such as hexane (the modern tech-

nique usually employed in developed countries) or by screw press (a lower-yield technique used at small extraction plants worldwide). Large processors refine the oil using techniques developed beginning in the 1940s. The removal of lecithin (itself used in many food applications—for instance as an emulsifier in chocolates) and other impurities is followed by bleaching and deodorization. The oil is then ready for use in salads and for home cooking. If hydrogenation is performed to enhance solidity and shelf life, soy oil can be blended with other oils to make margarine stock or shortening, including shortening for commercial deep-fat frying. Soy oil is also widely used in American prepared salad dressings and mayonnaises. Indeed, in the United States soy is by far the most commonly used oil in each of these applications. It is becoming increasingly popular worldwide because of its cheap price and high quality.

**Processing defatted soy protein.** Use of defatted soy protein has gone hand in hand with the development of large-scale hexane extraction of oil from the beans. Hexane, an organic solvent, dissolves the oil, thereby separating it from the soy protein. The hexane is then steamed out of the protein. Once desolventized, the protein is suitable for further refinement and processing into food-grade soy flakes, grits, defatted flour, concentrates (containing at least 70 percent protein), and isolates (containing at least 90 percent protein). Such products are used (1) in very small quantities as “functional” ingredients to improve the textures of a vast array of processed foods, including baked goods, soups, whipped toppings, and lunch meats; (2) as meat extenders in dishes for institutions such as schools and the armed forces; (3) as nutrition enhancers in products touted for their health benefits, such as protein-fortified breakfast cereals, weight-loss beverages, and “energy bars”; and (4) as the primary ingredient in dairy and meat substitutes (“analogs”). While some brands of dairy analogs are made directly from whole soybeans, others are made from defatted soy protein ingredients (or both). Those using defatted soy protein include some imitation cheeses, some frozen soy desserts, and soy infant formulas. American-style meat analogs, pioneered by scientists working for Henry Ford and by vegetarian Seventh Day Adventists, include soy burgers, steaks, “chicken,” hot dogs, sausage, “bacon” bits, and lunch meats.

### National Differences in Amounts of Soy Protein Consumed

Data from the United Nations Food and Agriculture Organization indicate that in 1999, North Koreans derived more daily protein per capita from soy than people in any other country (9.4 grams), followed by the Japanese (8.7 grams), Indonesians (7.2 grams), South Koreans (6.5 grams), and Chinese (5.1 grams). The many thousands of small tofu shops scattered throughout Japan, similar to bakeries in France, illustrate the dietary and cultural importance of soy protein to that society.

The rest of the world for which data are available had much lower rates of consumption in 1999, although some developing countries (for example, Libya, Uganda, Nigeria, and Costa Rica) have significantly increased their consumption in recent years. Average U.S. daily intake during that year was tiny but growing rapidly. Market studies suggest that soyfood sales are currently increasing at a rate of 30 percent per year in the United States.

### Research on Soy's Health Benefits

Soy is the only commonly eaten food containing high levels of isoflavones—compounds similar to human estrogen that have hormonelike effects. In the past decade, hundreds of scientific studies have examined the potential of isoflavones and other components of soy to reduce cancer risks, reverse tumor growth, prevent osteoporosis, mitigate unpleasant symptoms of menopause, and decrease the risk of heart disease. Findings in many areas are still equivocal, but results have been promising with regard to prostate cancer and, especially, heart disease. In 1999, the U.S. Food and Drug Administration permitted manufacturers of foods meeting certain criteria to make claims on food labels linking consumption of soy protein to a potentially reduced risk of heart disease.

Ironically, while soy protein holds promise as a disease-fighting food of the future, and although natural, unhydrogenated soy oil has healthful properties, the hundreds of millions of pounds of hydrogenated soy oil used yearly in the United States to deep-fry fast foods contribute to high cholesterol levels and a national epidemic of obesity.

### Future Directions for Soy

Many new varieties of soy are being developed, as conventional breeders and biotechnology companies focus on improving soy to benefit not only farmers, but also processors and consumers. Desired characteristics include improved shelf life and flavor of the oil; enhanced functional qualities of the oil for commercial food processing; improved nutritional profile for the oil or the protein; elimination of antinutritive elements and flatulence causing compounds; and reduction of soy's "beany" flavor. The new varieties are in differing stages of development; for some strains, the economic motivator is the improvement of animal feed or even the mitigation of environmental pollution caused by waste from animals fed conventional varieties. But much of the research has potential application to human foods.

Cultivating soybeans as a protein source for human foods is a significantly more efficient way to provide a population with protein than is raising mammals for meat: in the late 1990s, a pig raised in the United States required over three pounds of feed to produce a single pound of meat; a chicken required about two pounds. For this reason, soy has much greater potential than meat to provide critical protein to the world's hungry. The only

flesh foods that currently approach soy's efficiency for protein production are farmed fish.

Development workers have labored, with varying degrees of success, to introduce soybeans into the cuisines of protein-deficient populations. For example, the International Soybean Program (INTSOY) of the University of Illinois has worked extensively in Egypt, the U.S. Peace Corps has introduced soyfoods in Malawi, and the Mennonite Central Committee has had a long-term soyfoods project in Bangladesh. Since according to United Nations estimates world population will grow by some four billion in the twenty-first century, such efforts will surely increase.

**SPIRITS.** Distillation is the process of separating a liquid from a solid by boiling the liquid and condensing the vapors in another container to reform the liquid. The solid material that did not boil off is left behind. To the alchemist, the essence—or the spirit—of the thing was in the condensed vapors.

One can observe distillation in action when the steam from a teakettle condenses on a surface, such as the side of a refrigerator. The products of the distillation are the drops of water on white enamel and the mineral sludge that is left in the bottom of the kettle. (The word "distillation" is derived from the Latin *distillare*, 'to drip', and modern Italian retains the sense of the word as a 'concentration of the essentials'.)

Distillation can also be used to sort out mixtures of liquids that have different boiling points. If a mixture of alcohol and water is heated to more than 174°F but less than 212°F, the alcohol will boil and the water will not. If the vapors from the boiling are condensed and the condensate is collected, the collecting vessel will contain alcohol and the original cooking pot will contain water.

Imagine that the teakettle on the stove contains some boiling wine. (Wine is essentially a mixture of alcohol and water, the alcohol being derived from fermentation, by yeast, of the sugar in the grape juice.) If the temperature is kept below 212°F, the substance that boiled off would be mostly alcohol.

The social ramifications of absinthe and its powerful mind-altering effects were captured in this painting of a late-nineteenth-century Paris café by Edgar Degas (1834–1917). © MUSÉE D'ORSAY, PARIS/ART RESOURCE

The simplest kind of alcoholic distilling apparatus is not much different from a teakettle. It is called a pot still, and it consists of a kettle loaded with a mixture of alcohol and water. The alcoholic steam, however, is not released into the air. Instead, the steam leaves the boiling chamber and goes into a long, downward-spiraling tube, where it cools and condenses back into a liquid. This liquid, called the distillate, is a mixture of alcohol, water, and substances called congeners, which are by-products of fermentation. However, as the alcohol evaporates, the boiling temperature of the mixture rises, and by the end of the batch, a lot of water vapor has boiled off and been condensed along with the alcohol. Thus, the by-products of fermentation—congeners—end up in the distillate. In the twelfth century an Italian physician, Salernus, discovered that the cooling action could be facilitated by spraying the tube with cold water or building an external tube through which a stream of cold water could flow.

Historically, there has been no liquid that is at once as ordinary and as precious as wine. Arnold de Vila Nova, a thirteenth-century alchemist, wrote of distilled wine

## ABSINTHE

Ancestor of anise-based pastis, absinthe was the most popular and most notorious liquor in the nineteenth century, and possibly this combination of traits served to establish its reputation as the most notorious in history. Finally banned by the French government in 1915 because it was considered so harmful to one's health—it was 72 percent alcohol, or 144 proof—absinthe is inextricably linked to the artistic and literary life of Paris during the second half of the nineteenth century.

A favorite drink of Henri de Toulouse-Lautrec, Vincent van Gogh, Arthur Rimbaud, and Paul Verlaine, absinthe was popularized by French soldiers returning from Algeria in the 1830s. While stationed there, they had been prescribed the plant-based alcohol as an antiviral, antifever remedy, which they mixed in their drinking water. Upon returning to France, their taste for “*la fée verte*” (the green fairy), so named because of the drink's yellowish-green hue, soon spread throughout France to the general public, who sipped it sweetened with a lump of sugar in cafés. Crossing socioeconomic as well as gender lines, absinthe was enjoyed by all, from the top-hatted, well-fed factory owner to the penniless, tubercular laundress.

Absinthe was generally sipped as an aperitif between 5 o'clock and 7 o'clock in the evening. But those who were addicted drank it at any hour of the day, often consuming up to a dozen glasses in a single day. Part of the appeal of absinthe surely stemmed from the ritual surrounding its consumption. Unlike cognac, whiskey, gin, or eau-de-vie, which were imbibed in ordinary, shot-type glasses, absinthe was enjoyed in stemware designed expressly for the liquor. With an elongated cup measuring about four inches in height, the narrow, footed glass had a small depression at the bottom used to measure a dose of absinthe.

The liquor itself was clear, but when mixed with water, which was the customary way of drinking it, it turned cloudy and opalescent. First the absinthe was poured into a glass, and a perforated spoon was laid across the rim of the glass. Onto this spoon a lump of sugar was placed. Water was poured slowly over the sugar, which would

melt into the glass and sweeten the drink. The long-handled spoon would then be used to stir the contents of the glass, at which point the drink turned cloudy.

With the increasing industrialization of alcohol as the century wore on and the subsequent lowering of prices, alcohol consumption of all kinds rose rapidly in France, making it the most “alcoholic” of all nations in the world by the end of the nineteenth century. Absinthe came under attack by the French Temperance Society and was the only alcoholic beverage officially banned in France. But the ban referred only to consumption and not to production, and in the late twentieth century some distilleries resumed production, but for export purposes only.

By the early twenty-first century about thirty brands of so-called absinthe were produced in countries where production was still legal. In addition to France, the Czech Republic, Bulgaria, and Spain distilled it. The Old Absinthe House in New Orleans, with its great, ornate water fountain in the center of the room, is a vestige of America's absinthe culture, which was introduced by the Louisiana French. After enjoying a certain degree of popularity at the turn of the century, the drink was banned in the United States in 1914, around the time most European countries also made it illegal.

The world's only absinthe museum (Le Musée de l'Absinthe), owned and operated by Marie-Claude Delahaye, is in Auvers-sur-Oise, France, an hour from Paris in the village where Van Gogh died and is buried. The tiny museum displays authentic glasses, spoons, absinthe fountains, and bottles with period posters advertising various brands of this unique liqueur.

*Alexandra Leaf*

and its restorative properties, calling it *aqua vitae* or “water of life.” Chinese sources from about the same time mention a “wine” that could be ignited.

The chronology of distilling is not settled firmly, for there is archaeological evidence that the Minoans and Egyptians practiced distillation, which may suggest a very early understanding of the process. It can be said with certainty that by the fifteenth century distillation had

spread across Europe. Every region that had sufficient wood to fire a still developed a distilled version of its own wine or beer.

The simple still described by Salernus, called an “alembic” or pot still, was refined to permit redistillation and continuous loading and operation. The modern column still is capable of producing an almost pure and relatively tasteless alcohol.

The "Ohio Whisky War" made national headlines when the women of Logan, Ohio, carried the cause of Temperance to the doorsteps of local taverns. They are shown here singing Temperance hymns. From *Frank Leslie's Illustrated Newspaper*, 21 February 1874. ROUGHWOOD COLLECTION.

All of these early alcoholic substances were taken as medicines, if they were consumed at all, or were used to dissolve medicinal ingredients. They probably tasted unbearably harsh unless moderated with a dosage of sugar (another medieval novelty). It would be a century or two before refinements in the distillation process and the introduction of aging produced spirits that could be consumed in a pure form.

### Aging

When spirits age in wooden barrels, maturation results from an interaction of the original mix of alcohol and congeners with the wood and the small amount of oxygen that enters the barrel. The more intense the original flavors, the greater need there is to moderate the effects of wood and air. Once spirits are removed from

the breathable casks and put into bottles, no further maturation takes place. A bottle of ten-year-old rum purchased five years ago is still ten years old on the inside.

In the United States, small, new oak barrels are the norm for aging spirits in this manner. The wood has lots of extract to contribute to the finished flavor. Scotch whiskey, cognac, and rum are typically aged in older, larger barrels that have less oak flavor. When they were new, these barrels may have been used for storing wine.

Some governments specify storage time for spirits. The United States and Canada require a two-year storage period for most whiskey. Scotland and England mandate three years and Ireland five. Aging is never required for gin and vodka: In the case of these spirits, the problem of harsh flavors is addressed through precise column

distillation and charcoal filtration. Brandies are typically aged for three to five years, but some are held in cask for twenty-five years or more.

Aging in dry warehouses promotes the evaporation of water, thereby increasing the alcohol content; humid storage encourages the opposite. After aging, spirits are diluted to the strength at which they will be sold, blended to achieve their final taste profile, and colored for uniform appearance.

### Alcohol

Ethyl alcohol is the natural by-product of yeast acting on sugar in a water solution. This process is called fermentation, and it proceeds until either the yeast runs out of sugar, the alcohol concentration rises to the point where the yeast can no longer work, or the fermentation is artificially halted. The alcohol that most people drink is an organic chemical,  $C_2H_5OH$ . In 1536 the German alchemist Paracelsus first used the word “alcohol” in its modern sense.

Of great concern to alcohol producers and consumers is “how much alcohol is in this drink?” In the United States, containers of spirits are required to display the alcohol concentration of the drink as a percentage by volume. Alternatively, the strength of alcohol can be expressed as “proof,” which is twice the percentage by volume: for example, 100-proof spirits are 50 percent alcohol by volume.

**Alcohol and the brain.** There are two reasons that alcohol has been so popular for so long. The first is that aside from wine or beer, alcohol was one of the few drinks upon which early civilized humankind could rely. A large sedentary population pollutes its own streams and ground water; deadly typhoid and cholera bacteria thrived in drinking water. Milk was unreliable and, for many adults, not digestible. Fruit juice, in the days before preservatives, was either turned into vinegar through bacterial activity or turned into wine by fermenting through its own yeasts. Only wine, which does not support any bacteria harmful to man, was consistently safe for consumption.

In places where grapevines did not grow, a hot-water extract of sprouted barley grains was used to make alcoholic beverages. The heating process activated enzymes that converted starch to sugar and sanitized the water from which it was made. This solution of barley sugar would also ferment in the presence of airborne yeast. When it did ferment, it was called beer. This beer probably did not resemble the modern beverage of the same name, but it was certainly safer to drink than water.

Of course, ancient cultures did know of other technologies that could have possibly sanitized the beverage supply. For example, the Chinese boiled water and infused it with herbs as both a culinary and sanitary device. However, the manufacture of alcoholic beverages triumphed over all of them for reasons that had nothing to do with sanitation. Alcohol’s ability to demolish inhibi-

tions, inspire enthusiasm, and encourage sociability lies at the heart of and accounts for the transcendence of the beverage business. People drink in company because both the drink and the company become more pleasant in the process.

**Prohibition.** Like other milestone inventions, alcohol is not entirely a blessing. In addition to the lightened spirits and occasional hilarity of moderate drinking are the recklessness of excessive drinking and drunkenness.

Some people deny some of alcohol’s manifest virtues. Many people find the altered state of consciousness that alcohol induces to be threatening. Such a state brings out things in themselves and other people that they would rather not have called forth. People consuming alcohol are more likely to be sexual and boisterous. They are also more likely to be aggressive or otherwise obnoxious.

It is a short step from being repelled by one’s own impulses to wishing to eradicate or at least camouflage them in others. In the United States that impulse, coupled with a prejudice against wine- and beer-drinking immigrants, led to the adoption of the Volstead Act in 1919, which made the sale and possession of alcoholic beverages illegal.

Prohibition was the thirteen-year period during which there was no legal beer, wine, (apart from that used in religious services), or spirits consumed in the United States. This movement had profound and lasting effects on the U.S. beverage industry. It changed U.S. tastes and created a nation of whiskey drinkers. Since it is easier to traffic in small volumes of a highly concentrated illegal substance, distilled spirits became more available and more desired.

### Brandy

Brandy is a spirit distilled from wine. The source of the wine is usually grapes but it can be derived from any fruit. Dutch and English merchants in the seventeenth century promoted the production of brandy in the areas around the little towns of Cognac and Armagnac. Cognac produced an almost flavorless wine that yielded a relatively clean distilled product. Armagnac had no wine-growing tradition, but it did have large forests to fuel the alembics (used for distillation), as well as local farmers who saw the value of commerce.

Cognac at one time was a fiery, intensely flavored drink that combined complexity and power. It has since been tamed to compete with the smooth whiskeys in the American market, and brandy drinkers looking for intensity increasingly order Armagnac.

### Whiskey (Whisky)

Whiskey (Whisky) is distilled from beer, which is itself a fermented drink made by converting the starch of grains into sugar and then introducing yeast. If the conversion process involves sprouting the grain and then toasting it, it is called “malting,” and the result can be labeled “malt

## COGNAC DECANTERS

Anything as rare and fine as cognac is bound to be surrounded by some paraphernalia. One of the nicest accessories in the liquor business is the lead crystal decanter filled with amber-gold liquid. Set on a white tablecloth, the crystal catches and refracts the room light and turns the cognac ritual into a ballet of sparkles. The colors and the magnificent weight of the decanter make the drink (and by extension, the host) seem very important.

Alas, researchers have discovered that the lead that makes the decanter weighty and sparkly dissolves in the cognac over a period of time and ends up inside the consumer. Unfortunately, this lead is also poisonous.

whisky.” If the whisky is bottled unblended as the product of a single malt house, it can legally be called “single malt.”

The word “whiskey” or “whisky” is derived from a direct translation into Gaelic (*uisge beatha*) of Vila Nova’s *aqua vitae*. It is fitting that a Gaelic word is used here, since the spiritual home of whisky is Scotland and Ireland. The characteristic smoke and iodine flavors that are introduced during the making of the malt have created a peculiar and distinctive spirit that was at the height of fashion at the end of the twentieth century.

It is easy to account for the rise of Scotch whisky in general and single malts in particular: They are both expensive and exotic. Both types of whisky are produced almost by hand, in very small amounts, in two countries to which many Americans have a romantic attachment. Single malts are also expensive and the very epitome of an acquired taste. It is also easy to see the cause of their eventual downfall in the popular mind: They do not taste very good. Often they are described as having a taste between seaweed and peat smoke.

In colonial America, West Indian molasses was abundant, and the coastal drink was rum. Westward expansion after U.S. independence allowed for the cultivation of corn well in advance of a transport system that could carry it cheaply to market. Farmers on the frontier (then in Allegheny County, Pennsylvania) saw rye and corn-based whisky as a condensed and easily transportable cash crop. Their iron-free water supply helped to make that whisky appealing, and tax disputes with the new federal government in 1794 only entrenched the drink as part of an ongoing culture of rebellion.

Bourbon whisky is the product of Kentucky refugees from federal taxation. Their rye crops failed, but their corn whisky, called bourbon after the county where it originated, triumphed. Its cult is threatened only by the generalized decline in the spirits market.

## Gin

Gin was the first industrially produced spirit. The same Dutch traders who created cognac developed this continuously produced neutral spirit (one without a flavor characteristic). Gin was distilled from grain through a matrix of crushed juniper berries, called *genever* in Dutch. In England, a government that did not tax grain or distillation encouraged the availability of cheap gin. In the mid-eighteenth century, gin’s availability not only undermined local brewing, but it encouraged a wave of drunkenness among the newly urbanized poor that upset the gentry.

Gin remains the spirit of choice in England, where it is mixed with tonic or served “on the rocks” (over ice). In the United States, the martini dominates the gin market. Officially, it is a mixture of gin and vermouth shaken over ice and decanted to a dedicated, triangular martini glass. In practice, the vermouth is vestigial and save for differences in serving temperature and glassware, the martini is not much different from the plain gin that scandalized Georgian London.

## Vodka

The key to vodka-making is the charcoal filtering of the distillate to remove any traces of flavor. The original starch that supplies the sugar for fermentation can come from grain, potatoes, or even directly from sugar itself.

Vodka is defined in U.S. law as a flavorless beverage, but that has not stopped the marketing of more and more expensive “flavorless” vodkas or the development of an army of flavored variations. One brand, Absolut of Sweden, has recognized that in the absence of any real difference, it is important to make distinctions among brands; to this end, the manufacturer has created a long-running ad campaign that presents its distinctively shaped bottles as interpreted by various artists.

## Tequila

Young Americans have enthusiastically embraced tequila, an icon of Mexican culture, as a “bad-boy” drink. Cheap tequilas, distilled from pulque, the fermented sap of the blue agave plant, are allowed to contain up to 49 percent alcohol. More expensive versions are wood-aged and based entirely on agave starch. In Mexico there is a delimited tequila district. Any distilled pulque made outside of this area is simply called “mescal.”

## Rum

Sugar cane was being planted in Puerto Rico, Cuba, and Hispaniola a few years after Columbus arrived. The Spanish had learned about cane when they were an Arab

colony, and they brought cuttings from the few small cane gardens to these areas from the homeland.

Sugarcane becomes sugar when it is crushed and its juice is extracted. The juice is reduced through boiling, and the sugar then crystallizes. The liquid left behind is called molasses, which contains about 5 percent sugar. Along with the fermentable sugar, this molasses contains the concentrated flavor of the cane itself and the flavor of sugar caramelized during the reduction of the original juice.

Fermented molasses is, with a few exceptions, the raw material of rum. Traditionally, molasses was fermented by wild yeasts in a slow fermentation process that introduced its own complex flavors. This is still the practice for most premium rums. Most modern-day rum is produced by distilling molasses in large column stills that operate continuously. These stills turn out a high-proof, highly refined, and neutral-tasting product that can be as much as 190 proof (95% alcohol). This is the rum that is mixed with three different kinds of fruit juices and served with a little paper umbrella on the edge of the glass. It is sometimes wood aged and sometimes very good. It is certainly an excellent foil for juices and sodas.

A small amount of the world's total rum production is made in pot stills. These stills are loaded with a batch of fermented molasses, which is then distilled at a fairly low 140 to 160 proof (70–80 percent alcohol). The rum is then aged in old wooden barrels. The results are said to rival cognac in complexity.

**SQUASH AND GOURDS.** Cucurbitaceae is a highly specialized and unique family of mainly trailing plants of subtropical or tropical, moist or dry habitats. Plants bear mostly palmately lobed, alternate, and simple leaves and have spiraling tendrils. Plants are mostly

monoecious with yellow flowers, but sometimes with white petals, and inferior ovaries. The fruits are specialized berries called pepos and are of variable size. Some are among the largest fruits produced by any plant group. Because of their ability to produce large fruits, they lend themselves to competition. By the early twenty-first century the largest recorded fruit, which weighed a phenomenal 1,140 pounds (517 kilograms) was grown by Dave Stelts of Leetonia, Ohio, in 2000.

#### Plant Descriptions

*Cucurbit* is a general term used to describe all members of the Cucurbitaceae family, which includes the common vegetables cucumber, melon, and watermelon as well as the focus of this section, squash, pumpkin, and gourd. The common names in the three genera and seven species that represent the subject of this essay overlap considerably.

Products commonly called squash, pumpkin, or gourd are found in four of the seven species. The gourds are the source of least confusion since they are more or less readily identified by appearance regardless of species. Squash and pumpkin are used interchangeably depending on local custom. The sole exception is the decorative or Halloween pumpkin *Cucurbita pepo*, which is always referred to by that name. Defining characteristics of the cultivated *Cucurbita* species are in Table 1. Within squash it is useful to differentiate between summer and winter types. The summer types (yellow, zucchini, or scallop) are fast maturing, have soft rinds, are consumed when the fruit is immature, and are quite perishable. On the other hand, the winter squash take longer to mature, one hundred days versus fifty days, have a long storage life, several months versus two weeks, are consumed when the fruits and seeds are fully mature, and have durable rinds. Any confusion that may exist is among academics who quibble over nomenclature. Retailers, consumers, and cooks generally differentiate among squash, pumpkin, and gourd, and if not little damage is done.

#### History, Ethnography, and Symbolism of Production and Consumption

The word "pumpkin" is derived from the Old English *pompion* (originally Latin *pepo* and Greek *pepon*) and refers to a large melon or gourd. It was originally applied to the genus *Legenaria* but was later transferred to the New World *Cucurbita*. The more general word "squash" is a derivation of a New England Native American term "*askutasquash*," meaning vegetables consumed while green, in other words, a summer squash. Cucurbits have cultural and economic significance cross-culturally. Ralf Norrman and Jon Haarberg (1980) examined the symbolic place of cucurbits in Western literature and culture and further extended their analysis to selected non-Western cultural settings. They noted that cucurbits have complex semiotic associations with sex and sexuality, fertility, vitality, moisture, creative power, rapid growth, and sudden death. Cucurbits also figure prominently in the symbolism and cosmologies of many non-Western societies.

TABLE 1

Some defining characteristics of the cultivated *Cucurbita* species

Species	Seed	Leaf	Stem	Peduncle	Fruit flesh
<i>C. argyrosperma</i>	Large, white, prominent margin that may be scalloped	Moderately lobed, short, soft pubescence	Hard, angular	Hard, corky, sometimes swollen	Very coarse, pale yellow
<i>C. ficifolia</i>	Black or tan, smooth margin	Deeply lobed, smooth margin, round, prickly	Hard, grooved	Hard, angled, slightly expanded at fruit attachment	Coarse, stringy, white
<i>C. maxima</i>	White to brown, oblique seed scar	Almost round, unlobed prickly	Soft, round	Round, corky, not flared at fruit attachment	Fine, not fibrous, deep orange
<i>C. moschata</i>	White to brown, rough margin, oblique seed scar	Shallow lobes, almost round, soft pubescence	Hard, ridged	Hard, angled, flared at fruit attachment	Fine, not fibrous, deep orange
<i>C. pepo</i>	Light tan, prominent smooth margin, rounded seed scar	Deeply lobed, very prickly	Hard, ridged	Hard, angled, ridged	Coarse, orange

Squash was domesticated in a variety of New World sites, including central Mexico, Peru, and the eastern United States, as early as 10,000 B.P. (Smith 1997). The more specific timing, locations, and hypothetical dynamics of the domestication processes of the five principal species of domesticated squash are reviewed in a number of texts. Squash, along with maize (corn) and beans, formed the staple carbohydrate cores of Mesoamerican crop complexes that were the basis for state formation in the region (Scarre and Fagan, 1997). These cultigens were also significant food sources for precontact Native Americans in North America. Squash diffused to the Old World after 1492 through the networks of trade, migration, and commodity chains linked to colonialism and the expansion of global capitalism.

Squash is cultivated in the twenty-first century throughout the Americas, Europe, Africa, the Middle East, China, India, and Indonesia. Virtually all parts of domesticated squash, including fruits, seeds, flowers, and leaves, can be eaten. Cross-cultural culinary uses are quite varied. The fruits are typically boiled, sometimes fried or added to soups or curries. Squash is also the basis of candy and fermented beverages in Latin America. The seeds of squash are consumed raw or are cooked in various forms in China, India, and Mexico. Some Native Americans, most notably the Sioux of the Great Plains, traditionally flattened strips of fresh pumpkins, dried them, and made them into mats. Squash seeds are also used in a number of traditional folk medicine applications.

Pumpkins have an important place in the social history, folklore, and cultural symbolism of the United States. In early colonial New England settlers sliced off the tops of pumpkins, removed the seeds, filled the insides with honey, milk, and spices or fruit and then baked

the pumpkin in the hot coals of an open fire. Pumpkins were therefore the crust and not the filling of the early precursors of pumpkin pie. Settlers also used pumpkins in beer, breads, puddings, cookies, and many other foods, including pumpkin sauce, that is, pumpkins stewed with butter, vinegar, and spices. Many of these uses of pumpkins continue in the North American diet in the twenty-first century. The most common nonfood use of pumpkins in the United States is for decorative purposes, including the carving of Halloween jack-o'-lanterns.

Gourds are among the world's oldest domesticated plants, dating back to at least 8000 B.P. Three principal genera of gourds, *Legeneria* (including the bottle gourd), *Trichosanthes* (including the snake gourd), and *Momordica* (including the bitter gourd), originated in the Old World tropics. They have a wide range of economic, symbolic, ritual, and artistic functions cross-culturally. For example, Sally Price, in her ethnographic study of the Saramaka of Suriname, analyzes how elaborately carved and decorated calabashes (in this case the tree gourds *Crescentia cujete*, which are not cucurbits) figure prominently in women's labor, production, artistic expression, ritual exchanges, status, and power relationships in this Maroon society (Price, 1993).

Snake gourds are cultivated in the humid tropics and subtropics of Asia, Latin America, and Africa. The young fruits are consumed boiled or in curries, the stem tips and leaves may also be eaten, and the roots and seeds have a wide range of uses in traditional medicine throughout Southeast Asia. Bitter gourds were domesticated in Asia and diffused to the New World via the transatlantic slave trade. They are popular vegetables throughout India, China, Asia, Africa, the Middle East, Latin America, and the Caribbean. As with snake gourd, the plant is used

both as food and in a range of medicinal applications cross-culturally.

Bottle gourd was widely distributed as an early cultigen throughout the New World but is generally believed to be of African origin. It remains unclear as to how the bottle gourd diffused from Africa to the New World, although both human agency and oceanic drift currents have been proposed as mechanisms. Bottle gourd is principally used as a “bottle or container for both liquid and dry materials” (Heiser, 1979, p. 71) but also for food, floats, musical instruments, medicine, artistic expression, and in some cultures penis coverings. Among the Dani, an indigenous culture of highland western New Guinea (Irian Jaya), “from the age of four or five, males wear a *bolim* or penis gourd at all times except when urinating or having sexual intercourse” (Heider, 1979, p. 56). Karl Heider notes that each Dani man owns “whole wardrobes of penis gourds of different lengths and shapes . . . and the gourd itself is not a focus or symbol of masculinity or sexuality.” In the late twentieth century, Dani men continued to wear penis gourds in public, in defiance of Indonesian government attempts to ban the coverings, as a symbolic resistance to Indonesian state control over the region. In many societies bottle gourds have generally been displaced by the use of plastic and other industrially manufactured materials except in poorer regions or where gourds continue to have local cultural, ritual, or artistic significance.

### Horticulture

Squash, pumpkin, and gourd are produced worldwide in temperate, subtropical, and tropical climates. They constitute an important but not life-sustaining part of the diet for many cultures. Production data is probably not reliable because these products do not usually enter into international commerce and are relatively minor in importance. For example, production data became available in the United States for these crops only in 2000. Michigan and New York are the leading producers of decorative pumpkins, and Georgia and Florida are the leading producers of summer squash. The available world data show that in the early twenty-first century Asia was the principal producer of these cucurbits and that China and India accounted for nearly half of the reported world production.

The nutritional value of these cucurbits on the whole is not exceptional since they are mostly water. Pumpkin fruits, flowers, and leaves and winter squash fruits are, however, good sources of vitamin A, which may be scarce in the diets of those in some developing countries. Pumpkin seeds are rich in protein, fat, and carbohydrate but usually are not consumed in large quantities. Many cucurbits are low in fat and carbohydrates, which makes them useful in diets of those concerned with weight control in developed countries.

The principal *Cucurbita* species may be further grouped according to horticultural traits (Table 2). Fruit

The white-flowering *zucca rampicante* (vining gourd) or *zucca a tromba* (trumpet gourd) is an Old World cucurbit (*Lagenaria siceraria*) that has been grown in the Mediterranean region since ancient times. The edible baby gourds, shown here, were known as *zucchette* or *zucchini* in Italian and were the breeding model for the New World squash grown today under the name of *zucchini*. PHOTO WILLIAM WOYS WEAVER.

shape and color and rind durability are the main discriminating characteristics. Some of the types are arbitrary and of historical interest only. For example, cushaw squash, winter crookneck squash, and marrow squash are not commonly grown, but they may be regionally important. The gourds and pumpkins of *C. pepo* are mostly grown for ornamental rather than culinary purposes and are increasing in economic importance in the United States. Show pumpkins are grown exclusively for competition in the heaviest-fruit contests held in various parts of the United States. Note that the word “pumpkin” or “squash” has been attached to each type. Some may disagree with these designations. The hard-rind types are generally called winter squash, whereas the soft-rind types (cocozele, crookneck, scallop, straightneck, vegetable marrow, and zucchini) are generally referred to as summer squash. Winter squash are mostly indeterminate

TABLE 2

Horticultural types in <i>Cucurbita</i> spp.			
Species	Type	Description	Typical Cultivars
<i>C. argyrosperma</i>	Cushaw squash	Striped, green or white hard rind. Pear shaped or with a straight or curved neck.	Green Striped Cushaw (Figure13), Japanese Pie, Tennessee Sweet Potato
<i>C. moschata</i>	Tropical pumpkin	Round, oblate, or irregular shape. Green, buff, yellow, or piebald hard rind.	La Primera, Seminole, Solar, Borenquin
<i>C. maxima</i>	Cheese pumpkin	Variable shape, smooth, hard, buff-colored hard rind.	Dickinson, Kentucky Field
	Neck squash	Long curved or straight neck. Smooth hard rind fruit, usually buff.	Golden Crookneck, Winter Crookneck, Waltham Butternut, Zenith, Ultra
	Banana squash	Elongated fruit pointed at the ends. Orange or pink moderately hard rind.	Banana, Pink Banana
	Delicious squash	Top shaped. Orange or green hard rind.	Delicious, Golden Delicious
	Hubbard squash	Round in the middle tapering at each end. Blue, orange, or green hard warty rind.	Hubbard, Blue Hubbard, Golden Hubbard
	Marrow squash	Lemon-shaped with orange hard rind.	Boston Marrow
	Show pumpkin	Very large globular, sutured, light orange fruit. Moderately hard rind.	Atlantic Giant, Big Max
<i>C. pepo</i>	Turban squash	Turban shaped with a large button. Hard rind.	Turks Turban, Warren, Turks Cap
	Acorn squash	Acorn-shaped, grooved fruit. Dark green, orange, or white hard rind.	Table Ace, Tay Belle, Heart of Gold, Table Gold
	Cocozelle squash	Long, cylindrical, bulbous blossom end. Striped or variegated green soft rind.	Cocozelle, Long Cocozelle
	Crookneck squash	Elongated with narrow curved neck. Yellow soft rind.	Dixie, Yellow Summer Crookneck, Supersett
	Ornamental gourd	Variously shaped and colored. Smooth or warty hard rind.	Egg, Striped, Pear, Bicolor, Spoon, Orange Ball, Crown of Thorns, Warty
	Pumpkin	Large, round, oval oblate shape. Mostly orange, sometimes white relatively soft rind.	Connecticut Field, Small Sugar, Howden, Jack-Be-Little
	Scallop squash	Flattened with scalloped margins. White, yellow, green, or bicolored soft rind.	White Bush Scallop, Peter Pan, Sunburst
	Straightneck squash	Long, cylindrical, yellow soft rind.	Enterprise, Goldbar, Early Prolific Straightneck, Multipik
	Vegetable Marrow	Short, tapered, cylindrical. Light green to gray soft rind.	Clarita, Goya, Zahra, Caserta
	Zucchini squash	Uniformly cylindrical. Green or yellow soft rind.	Dividend, Revenue, Spineless Beauty, Gold Rush

or vining in growth habit, and summer squash are mostly determinate or have a bush growth habit.

Squash and pumpkin are frost sensitive, so field establishment by seeds or by transplants two to four weeks old is made when no threat of frost remains. Summer squash plants are spaced three feet (one meter) apart in rows six feet (two meters) apart, and winter squash plants are spaced six feet apart in rows six to nine feet (two to three meters) apart. Local recommendations for crop management should be followed. Wild or domesticated bees are necessary for pollination and subsequent fruit enlargement since separate staminate (male) and pistillate (female) flowers occur on these plants. Baby squash, harvested when the flower opens or shortly thereafter, do not require pollination.

With good growing conditions, summer squash should be ready for harvest in about forty days from establishment. Fruit should be harvested about six to eight

days after pollination, when they are small and the rind has a distinctive sheen. The rind becomes dull in over-maturity with a concomitant loss of quality. Summer squash should be consumed soon after harvest for best quality but may be kept in a plastic bag in a home refrigerator for a few days. Summer squash fruits should be harvested every day or two in warm weather.

Winter or hard-shelled squash, because they are grown to maturity, require much longer to produce a marketable product, 80 to 110 days, depending on weather and cultivar. Fruits should be harvested when fully mature (when seeds are fully developed) but before they are injured by frost. Winter squash, unlike summer squash, have a long life after harvest. Storage at or near 50°F (10°C) and 50 percent relative humidity retains quality for several months. For instance, the tropical pumpkin (*C. moschata*) fruits have remained in good condition for two to three months in a garage in Florida in uncontrolled conditions.

## Plant Improvement

The economically important types showed marked genetic improvement in the last half of the twentieth century. Previously improvement had been mainly by selection, first from wild types and later from landraces.

The use of F<sub>1</sub> hybrids allows incorporation of dominant genes from two parents into the hybrid. For example, earliness in one parent can be combined with high culinary quality in the other parent to produce a superior hybrid. Often cited advantages of hybrids include uniformity, earliness, disease resistance, and intense fruit color. The *B* gene, originally obtained from an ornamental bicolor gourd, has been used to obtain bright yellow color in many *C. pepo* types. Exclusivity is usually not listed among the advantages of hybrids, but since the developer controls both parents, the hybrid cannot be duplicated by others. This fact provides the economic incentive for private development and competition among seed companies. Hybridity has been exploited most fully in cultivar development in summer squash, especially zucchini squash, and in decorative pumpkins.

Traditional plant-breeding techniques are most commonly utilized for improvement of these cucurbits. However, transgenic summer squash with resistance to cucumber mosaic virus, watermelon mosaic virus, and zucchini yellow mosaic virus have been developed and are used in areas where these diseases are a severe threat.

**STAPLES.** Staple foods are those that appear most often in a given diet and provide its highest energy content. Satiety is the state sought from their consumption. A good example of an optimum staple are the loaves made from thick red sorghum porridge (*Sorghum caudatum*

[Hack Stapf]) that the Masa in northern Cameroon consume. The flour is unsieved on purpose so that it takes longer to digest. Insufficient staples in the diet leave the consumer unsatiated; it is when staples are lacking that famines occur.

### Ambiguity of the Concept

The concept of a staple can be considered in two ways: (1) as the raw food material that is most often consumed and that brings the highest energy contribution to the diet and (2) as the most common dishes made from it. In Europe, wheat is a staple. For the French, bread is the wheat staple, and for the Italians, pasta is the usual foodstuff produced from it. In Africa, sorghum is a staple, and the Masai use it to make daily loaves.

It should be mentioned that staple foods are typically accompanied by a relish providing palatability and flavor. In Chinese culture, the idea of food is illustrated by the combination of two words: *fan*, meaning grain (or rice), and *tsai*, meaning relish (Chang, p. 7). This association of a staple with a relish may be observed in many cultures.

In traditional societies, the primal cuisine consists of preparing and making palatable the staple foods according to local criteria. In Senegal, pearl millet is cooked in many ways, using various kinds of flour and semolina. It can be steamed, or cooked in water or oil. In Mexico, maize used as grain or flour permits the preparation of countless dishes.

### Types of Staples

In many societies, staple foods are of plant origin. However, among the Inuit, meat and fat can be considered staples (Robbe, pp. 101, 184), and for pastoralists like the Ariaal, Turkana, and Maasai of East Africa, milk is a dietary staple, representing over 50 percent of food calories (Little et al., p. 74). Similarly, milk may be regarded as a staple commodity for Mongolian herders (Accolas and Aubin, pp. 55–83).

Among most hunter-gatherers, plant foods provide the highest amount of calories in the diet and, according to their seasonal availability, many species therefore assume the role of a staple. In the Central African Republic, pygmies rely on wild yams (*Dioscorea* spp.) for this purpose. The mongongo nut (*Ricinodendron rautanenii* Schinz) may be similarly regarded as a staple among the !Kung San of Botswana (Lee, p. 307).

Most fishing societies, although depending on predatory activities for their livelihood, use a carbohydrate as their staple—rice (*Oryza sativa* L.), for instance, in southern Asia (Firth 1966, p. 3).

### Storage

Since the Neolithic period, agricultural societies have produced and stored the elements of their diet. This is, for the most part, an easy matter with tubers, which re-

main planted in the fields and are only dug out as needed. Cereals and pulses, on the other hand, have to be protected from moisture, fungi, insects, and rodents. This is done by using granaries, some of which quite cleverly repel the pests. For instance, the *borreos* of northern Spain repose on pillars with an overhang, which prevents rodents from reaching the crop. In the Old World, where invasions were common, silos were dug into the ground and the opening hidden to avoid plundering (Gast and Sigaut). There are no optimal traditional solutions, however, and losses amounting to a quarter of the crop may sometimes be observed.

### Main Staples

Among staples, one is usually prevalent. This is the case of wheat (*Triticum aestivum* L.) in Europe, rice in Asia, maize (*Zea mays* L.) in Central America, cassava (*Manihot utilissima* Crantz) in South America or Africa. Yams (*Dioscorea* spp.) are a main staple in the Pacific (Pollock) and Africa. In 2001 the production figures for the main commodities used as staple foods on a worldwide basis were as follows: maize, 604 metric tons (Mt); rice (paddy), 585 Mt; wheat, 578 Mt; potatoes, (*Solanum tuberosum* L.), 304 Mt; cassava, 176 Mt; barley, (*Hordeum vulgare* L.), 138 Mt; sweet potatoes, (*Ipomoea batatas* [L.] Lam) 136 Mt; sorghum, 57 Mt; and pearl millet, (*Pennisetum* spp.), 28 Mt (information available at the Food and Agricultural Organization, or FAO website).

### Secondary Staples

Secondary staples, whose role is more seasonal, should also be mentioned. Some have been abandoned, others are still in use. For example, in Europe and the Near East, typical secondary staples include buckwheat (*Fagopyrum sagittatum* Gilib.), barley, true millet (*Panicum miliaceum* L.), and rye (*Secale cereale* L.), and also pulses such as broad beans (*Vicia faba* L.), lentils (*Lens culinaris* Medik.), and chick peas (*Cicer arietinum* L.). Common beans (*Phaseolus vulgaris* L.), which originated in America, also continue to flourish in Europe, where they often contribute protein to the diet of the poorest in society.

African secondary staples include hungry rice (*Digitaria exilis* [Kipp. Stapf]), finger millet (*Eleusine coracana* [L.] Gaertn.), cowpeas (*Vigna unguiculata* [L.] Walp.), and bambara groundnuts (*Voandzeia subterranea* [L.] Thouars). Soya beans (*Glycine max* [L.] Merr.) are the usual secondary staple in Asia.

In many tropical areas around the world, the plantain banana (*Musa paradisiaca* L.), tubers like the American cocoyam (*Xanthosoma* spp.), and taro (*Colocasia esculenta* L.) are consumed as secondary staples. Breadfruit (*Artocarpus altilis* [Parkinson] Fosberg) and jackfruit (*Artocarpus heterophyllus* Lam. L.) fulfill the same role in southern Asia and Oceania. The starch made from the pith of the sago palm (*Metroxylon* spp.) is also popular for a similar reason among various tribes in New Guinea.

Other secondary staples, though no longer in popular or widespread use, include the following: the European chestnut (*Castanea sativa* Mill.), a farinaceous fruit, consumed in southern Europe (Bruneton-Governatori, *Le pain de bois*), and the acorns of various oaks, for example, the California white oak (*Quercus virginiana* Mill.), that served as an important staple food for Native Americans (Hedrick, p. 480).

### Diffusion

Staple foods are not necessarily indigenous to the place where they are today most frequently consumed (Gariné, p. 240). For instance, maize, which has spread to southern Europe, Africa, and Asia, is native to Central and South America (Estrella, p. 72; Messer, pp. 97–112). Cassava, which found its way to Africa, southern Asia, and Oceania, also originated in South America. And, rather unexpectedly, potatoes and maize, which are nowadays staple foods for some Nepalese populations, are in addition of South American origin.

The routes and methods of diffusion for such staples is still a matter of discussion (Purseglove, p. 1; Chastanet, p. 265). It is likely that the way by which rice (native to southern Asia) reached the Mediterranean basin in ancient Rome will never be known, or why it only began to be cultivated in Lombardy in the sixteenth century (Barrau, p. 291), or how sorghum, native to tropical Africa, reached China (Simoons, p. 75).

The discovery of America contributed to the establishment of many new staple crops (Lewicki, p. 50) in the Old World after Christopher Columbus's voyage in 1492. For instance, maize was introduced at the beginning of the sixteenth century in Spain and especially Portugal, where it rapidly became a main staple. It also enjoyed widespread popularity in Turkey (in fact, maize was commonly known as "Turkish wheat" in Europe) and spread to Africa through the Nile Valley. It was later transported to the west coast of Africa by Spanish and Portuguese merchants.

More extensively documented was the introduction of potatoes (*Solanum tuberosum* L.), native to South America, to Europe around 1540 by the Spaniards. At first a medicinal product, they later became a food in Ireland, France, the Netherlands, and Germany during times of famine and a cheap source of nourishment for industrial workers in the nineteenth century (Messer, p. 191). They are now a staple in many Eastern European countries.

The slave trade contributed to the development of maize and cassava production in Africa as high-yielding crops to feed the slaves on their way to America (Bahuchet and Philippon, p. 92). Colonial America later focused on the development of staples (Firth, "Sociological Study") that were easily produced and drought-resistant, such as cassava, or easy-to-store and prepare, like rice, in order to feed cheap labor engaged in cash cropping, industrial manufacturing, and mining (Chrétien, p. 76).

In 2001 the export of staples from countries with sophisticated technology and powerful means of commercialization, as in the United States and Europe, motivates harsh competition in their sale to developing countries (Barrau, p. 300). Low price, widespread availability, easy preparation, and prestige in adopting the tastes of thriving industrialized countries are underlying factors in such food changes. The French, for instance, promoted the importation of wheat into Africa. The urban elite in many African nations developed an interest in French cuisine as a result. Today, bread is widely consumed in French-speaking Africa, and in Senegal it is even delivered by car to small villages.

### Prestige

In agricultural societies, the successful production of a staple formerly conferred prestige because it demonstrated technological skill and benevolent protection from supernatural powers. At harvest time, the display of vast quantities of yams still conveys success in the Trobriand Islands (Schiefenhoevel and Bell-Krannhals, p. 244) as it did seventy years ago (Malinowski, p. 171).

### Staples and Cultural Superfood

As previously indicated, in most cultures one staple food is dominant. Some populations are restricted to a small number of staples, as is the case with the Masai population already mentioned. They consume their thick sorghum porridge loaves at 90 percent of their meals. Most traditional societies nonetheless have to adjust their range of staples according to the season and the habitat. This enables the Tamang, who live in the middle hills of Nepal, occupying a watershed ranging from 1,400 to 4,000 meters, to consume a wide range of basic foods: rice, maize, taros, potatoes, barley, and wheat.

It should be stressed, however, that a single staple normally becomes a key symbol in most traditional societies. This is certainly the role of rice among the Tamang and in most of India, of maize in Central America, and of wheat in Europe. Such a staple is what Jelliffe (p. 279) very adequately termed "cultural superfood" and it exists in a population's food supply as a "central core food," as described by Passin and Bennett (p.113).

### Religious Aspects

Besides providing most caloric intake, a central staple also elicits emotional reactions in relationship to food: it is the "daily bread." Among the Masai, "to be alive" means eating the sorghum loaf. Its use is therefore strongly imbedded in their religious beliefs and mythologies.

Among the Serer of Senegal, pearl millet was considered a gift from god to prevent human starvation. Bread, made from wheat, is constantly referred to in the bible: It is a symbol of the body of Jesus Christ and also plays an important part in the Jewish Shabbat (Erich, p. 227).

As such, staples are considered sacred foods to be handled with care and respect. The Kanaks of New Caledonia formerly carried yams in their arms like infants, since the crop grew on the land in which their ancestors are buried (Leenhardt, p. 83).

Staples are also often associated with particular deities. In Mexico, among the Aztecs, Tlaloc, one of the central deities, was linked to maize. In Greek and Roman mythology, Demeter, Mother Earth (Ceres for the Romans), is associated with agricultural products, especially wheat, symbolizing the resurrection of Persephone (or Proserpine).

Although a staple may be a revered food in a culture and is consequently to be respected, it may also elicit other responses during certain periods. For instance, in many rural societies, the harvest, marking the end of an annual cycle of food production, is an important time of celebration. Among the Koma of northern Cameroon, while sexual promiscuity is to be avoided during the maturation of staples, the threshing activities provide an opportunity for boisterous celebration, setting the stage for more permissive behavior.

Staples are additionally used in most religions as offerings to supernatural beings. In rural European societies, first-fruit offerings were formerly made with wheat, which has also been identified in Egyptian tombs dating from the dynastic period (Darby et al., p. 486). Offerings prepared with maize are presented to the deceased on All Saints Day in Mexico. Millet and sorghum are offered to deities in the form of grain, porridge, or beer in many African cultures.

### Adaptability and Nutrition

Staple foods, the foodstuff to which infants are first introduced, are considered to be safe during weaning. They contribute to the development of a palate and organoleptic expectations. This can have important consequences in terms of food education and food relief programs, which might be more successful if they tried to provide the populations concerned with their own staples rather than those readily available or popular elsewhere.

In traditional societies, a staple is not necessarily chosen because it is the highest-yielding species with the best nutritional value. Many factors determine its selection. The elected staple might even provide little else than energy, as is the case with the false banana (*Ensete ventricosum* [Welw.] E. E. Cheesm.) among the Gurage of Ethiopia (Shack). In many areas of Africa, at the limit between the tropical savanna and equatorial forests, the cultivation of both maize and cassava is possible. Although the former is more nutritionally complete, it requires more work than the latter. Sometimes societies opt for the staple easiest to produce.

Since the staple, generally considered the safest food to consume, is also the first solid item offered to a child, its nutritional value may have important consequences

during the weaning period. In this respect, cereal staples, which contain proteins, provide better nutrition than tubers. Relying on a single staple food in a monotonous diet amplifies its nutritional weakness. The lack of the amino acid thiamine can provoke beriberi among rice eaters, and pellagra occurs among maize consumers through an inadequate amount of tryptophane (FAO, *Maize and Amino-Acid Content*). Cassava contains toxic cyanide, which has to be carefully eliminated before consumption to avoid health risks. The pulse *Lathyrus sativus* L., which is consumed mainly by the poorest in Central India, can cause a paralytic disease called lathyrism (Kaul and Combes).

### The Present Situation

Because of the significant progress in food production, distribution, and commercialization, it is possible today for anybody with financial means to consume any food, in any quantity, at any time of the year. The range has no limits. This minimizes the material importance of staple foods and the nutritional risks related to their exclusive consumption. What is the staple food of a European today? There has been a general worldwide decrease in the consumption of carbohydrates. As a result, someone living in present-day France is likely to eat only half the amount of bread an individual consumed in 1955, 63 kg per year as opposed to 122 kg. In France cereals represent only 23 percent of food energy, whereas in Italy that number is 32 percent (Collet-Ribbing and Decloitre). This difference is probably due to the maintenance of a very old style of eating in Italy, which combines an energy-rich staple like pasta with a relish of varied composition.

The globalization process has had a positive impact on food distribution worldwide by making a very wide range of foods and dishes available, but the choices made in some cultures as a consequence are not necessarily nutritionally sound. The greater consumption of white rice over brown rice and traditional staples, which contain more proteins, minerals, and vitamins, may have unforeseen negative nutritional consequences such as protein malnutrition and beriberi (FAO, *List of Foods and 1972 Food Composition Table*).

Today staples retain some of their religious and symbolic value. This is the case of bread among Christians, and rice among many populations of Asia. Consuming one's traditional staple food is also psychologically satisfying. This is why a number of emblematic dishes involving a cultural superfood are still consumed on social occasions, especially by immigrants. They exist as a token of the past, a demonstration of a lasting cultural authenticity.

**STARCH.** Starch is a highly organized mixture of two carbohydrate polymers, amylose and amylopectin, which are synthesized by plant enzymes and simultaneously packed into dense water-insoluble granules. Starch granules vary in size (1 to 100 microns [ $\mu$  m] in diameter) and shape, which are characteristic of their specific plant origin. Starch is the major energy reserve for plants; it is located mainly in the seeds, roots or tubers, stem pith, and fruit. Starch amylose is primarily a linear chain of glucose units. Amylose chains can coil into double helices and become insoluble in cold water. Amylopectin also is composed of chains of glucose units, but the chains are branched. This branched structure renders amylopectin soluble in cold water. The molecular architecture of the amylopectin and amylose within the granules is not entirely understood, but the granules are insoluble in cold water. The functional properties of native starch are determined by the granule structure. Both the appearance of the granules and their functional properties vary with the plant source.

### Physical and Functional Properties

In home cooking and in commercial food processing native starches are used for their thickening properties. Starch granules when heated in water gradually absorb water and swell in size, causing the mixture to thicken. With continued heating however, the swollen granules

Starch is not only a food thickener but is itself the focal point of numerous recipes. The introduction of cornstarch led to the popularity of cornstarch pudding during the nineteenth century, as shown by the picture on this 1883 pamphlet cookbook. ROUGHWOOD COLLECTION.

fragment, the mixture becomes less thick, and the amylose and amylopectin become soluble in the hot mixture. This process of granule swelling and fragmenting is called gelatinization. Once gelatinized the granules cannot be recreated and the starch merely behaves as a mixture of amylose and amylopectin. Because of the larger size of the swollen granules compared to the size of amylose and amylopectin, the viscosity of the swollen granule mixture is much higher than the viscosity (the resistance to flow or a liquid or semi-liquid mixture) of the amylose/amylopectin mixture. Starches from differ-

ent plant sources vary in their gelatinization temperatures, rate of gelatinization, maximum viscosity, clarity of the gelatinized mixture, and ability to form a solid gel on cooling.

The texture of heat-gelatinized starch mixtures is variable. Some gelatinized starch mixtures have a smooth creamy texture, while others are more pastelike. Some starches form gels after cooking and cooling. These starch gels may lack stability and slowly exude water through the gel surface. A similar breakdown of the gelatinized starch occurs in some frozen foods during thawing and refreezing. Although amylose is soluble in the hot gelatinized starch mixture, it tends to become insoluble in the cooled mixture. This phenomenon is called retrogradation and it occurs when the amylose chains bind together in helical and double helical coils. Retrogradation affects the texture of the food product and it also lowers the digestibility of the product. The proper starches must be employed for the different food products to minimize these problems. Certain starches are good film formers and can be used in coatings or as film barriers for protection of the food from oil absorption during frying.

### Native and Modified Starches

The predominant commercial starches are those from field corn (maize), potato, cassava (tapioca), wheat, rice, and arrowroot. Field cornstarch (27 percent amylose and 73 percent amylopectin) is the major commercial starch worldwide. Genetic variants of field corn include waxy maize, which produces a starch with 98 to 100 percent amylopectin, and high-amylose starches, which have amylose contents of 55 percent, 70 percent, and higher. Waxy starch does not form gels and does not retrograde readily. High-amylose starches retrograde more extensively than normal starches and are less digestible. Their linear structure enables them to form films.

From the 1940s on the demand for convenience foods, dry mixes, and various processed foods has led to the modification of starches for food use and for other commercial products. These modified starches improve the textural properties of food products and may be more suitable for use in modern processing equipment. The Food and Drug Administration regulates use of the various modified food starches by stipulating the types of modification allowed, the degree of modification, and the reagents used in chemical modification. However, the food label is required only to state that "modified starch" is present. Only a small fraction of the sites available for modification of the food starches are actually modified. Although the degree of modification is small, the properties of the starches are significantly improved. This small degree of modification is sufficient to give a more soluble and stable starch after cooking. The clarity of the gelatinized starch as well as the stability of the cooked starch and starch gels are improved. The modification procedures are carried out under mild conditions that do

not cause gelatinization of the native starch granules, and therefore the functional properties of the granule are preserved. The emulsifying properties of starch also may be improved by proper modification, improving the stability of salad dressings and certain beverages.

Physically modified starches include a pregelatinized starch that is prepared by heat-gelatinization and then dried to a powder. This instant starch is water-soluble and doesn't require further cooking. Because of its lower viscosity resulting from loss of granule structure, the starch can be used at higher concentrations. Certain confectionaries require high levels of starch to give structure to their products. These gelatinized instant starches serve this role. Cold water swelling starches represent a different type of instant starch. They are made by a proprietary process that retains the granule structure but lowers the granule strength. These cold water swelling starches give higher viscosities than the other instant starches. They are used in instant food mixes and for products such as low-fat salad dressings and mayonnaise.

Plant breeding has led to specialty starches with atypical proportions of amylose and amylopectin. Waxy maize starch with nearly 100 percent amylopectin is inherently stable to retrogradation. Chemically cross-linked waxy maize starch is a very high-quality modified starch. High-amylose starches have become available more recently and have led to lower caloric starches. Because of the crystallinity of these starches they are partially resistant to digestion by intestinal amylases and behave as dietary fiber when analyzed by the official methods of analysis for dietary fiber. Some of these high-amylose starches contain as high as 60 percent dietary fiber when analyzed.

The nutritional value of uncooked (ungelatinized) starchy foods (cereal grains, potato, peas, and beans) is relatively poor. Our digestive enzymes do not readily convert the native granular starch of uncooked fruits and vegetables into glucose that would be absorbed in the small intestine. Undigested starch passes into the large intestine where, along with dietary fiber, it is broken down to glucose and fermented to short-chain fatty acids. Some of these short-chain acids are absorbed from the large intestine resulting in recovery of some of the caloric value of the native starch.

### Starch-Derived Dextrins and Corn Syrups

Modified starches as described above were developed to improve starch functionality in foods as well as their ability to withstand the physical forces of modern food processing systems. In addition to the food applications of starches and modified starches, the native starches are also converted into other products that serve food and other industries. These products do not require the granular character of native starches, which is lost by chemical or enzymic action during processing of the starch.

Dextrinization, a process requiring high temperatures and acid that has been in use since the early 1800s,

converts native starch into dextrins that are composed of amylose and amylopectin chains of smaller sizes and altered structure. Consequently, food and nonfood industries have access to a range of dextrins of varying molecular sizes, solubility, and viscosity, but without the granular characteristics described above. Corn syrups are made in the same way as the dextrins, but they are converted to a higher degree such that glucose is a major ingredient. The more recent availability of an enzyme that converts glucose into fructose has led to a new industry in high-fructose corn syrups, which have found a strong market in beverages.

**STEW.** A stew has been described as an assortment of foods cooked in liquid within a container with a lid. Stews are usually made from several ingredients and may be named for the most important of these, for example, beef stew; for its point of origin, as in Irish stew; or for the pot in which it is cooked, as in Rumanian *ghiveci*, named for the Turkish *güvec*, an earthenware pot in which the stew is cooked.

The word "stew" is said to come from the old French word *estuier*, meaning to enclose. Most cultural groups have created a recipe for a special stew, and there are as many versions of them as there are cooks to make them.

In the Western world, meat stews are categorized as "brown" or "white." This means that the meat is browned in fat before liquid is added for the brown stew; meat for the white stew is not cooked in fat before liquid is added. Stews may contain meat, fish, or poultry; many of them, however, are meatless. There is also sometimes a fine line between stews and soups. Stews are usually thick, some so thick that they must be served on a plate and eaten with a fork. Others are served in soup bowls. Stews most often have several solid food ingredients. An exception is a seafood stew such as oyster or lobster stew, which contains fresh seafood, milk, and frequently butter.

Stews are commonly regarded as "comfort" foods, everyday dishes served to family or close friends in an

intimate setting, rather than as fare in a more public setting or at special occasions. An exception would be *boeuf à la bourguignonne*, usually referred to as beef burgundy in the United States, a dish that is considered exceptional enough to be served to a guest. This stew is made with beef, tiny onions, mushrooms, wine, and herbs. M. F. K. Fisher once wrote that stews can be good enough to be haute cuisine, or the opposite, a meal fit for the lowest echelon of society, the imprisoned.

There are several important advantages to stews: Less tender cuts of meat can be tenderized with the long, moist cooking; more expensive ingredients that may be available only in small amounts can be stretched by adding less expensive foods; meat cut in small pieces cooks faster; and one-pot cooking conserves fuel and makes cleanup easier. Stews may be cooked on top of a range, in an oven, over an open fire, or in an electric Crock Pot.

In addition to being versatile in their ingredients, stews are versatile in their uses. Suggested uses include as filling for tarts or patty shells, or over mashed potatoes, rice, or biscuits.

Usually considered dishes that must be cooked for long periods, stews are, in fact, cooked quickly in countries where fuel is scarce. There are Asian chicken stews, made with young and tender chickens, that cook quickly, but are even more worthwhile because they conserve energy since the entire meal can be cooked in one pot.

Because stews are apt to use protein- and carbohydrate-containing food, as well as ingredients high in vitamin and mineral content, they are good sources of nutrients. Combining certain ingredients, for example, rice and beans, can enhance the nutrients in each food, making them more usable by the human body. Water-soluble nutrients are consumed in the sauces, or gravies, that are part of stews.

## Kinds of Stew

**Europe.** In the eighteenth century, the term “made dish” was used to distinguish between a roast and various mixtures of ingredients. The made dishes in both France and England were often French stews, or ragouts, many still commonly served today. The term *daube* is more often used to describe beef stews in France. Patricia Wells’s *Bistro Cooking*, published in 1989, contains a recipe for a *daube* containing wild mushrooms and oranges. An Alsatian meat stew (beef, pork, and lamb cooked with vegetables) is a tradition on Monday, wash-day, in certain regions. A family’s stew pot is taken to the neighborhood bakery where the stew is cooked until noon, when a member of the family arrives to retrieve the meal.

*Navarin* is a popular French stew made with mutton, potatoes, and onion. In *The Food of the Western World*, Theodora Fitzgibbons tells us that if root vegetable are added, the stew should be called *ragout à la printanière*.

Bouillabaisse, the renowned Mediterranean fish stew of France, has its counterparts in the fish stews of Greece, Italy, and Spain. There is also a less well-known bouillabaisse made with monkfish and aioli, the French garlic mayonnaise. The reader should, in addition, be mindful that the terminology can sometimes be misleading: There is a *bouillabaisse de Tante Paulette*, which is actually a chicken stew flavored with fennel, saffron, and Pernod or another licorice-flavored liqueur, and was frequently served at a legendary Parisian bistro, and a rabbit bouillabaisse.

The German *Eintopf* is another one-pot meal or stew. In the 1930s Hitler urged Germans to return to the austere meals of former days. It became law in 1933 that one Sunday a month, from October to March, was *Eintopfsonntag*, one-pot Sunday. Money saved from not eating more lavishly was to be donated to the poor. *Eintopfs* are still popular in Germany, especially in the north. *Linsentopf*, lentil stew, and *Pichelsteiner*, made with beef, veal, lamb, and pork, are popular forms of *Eintopfs*.

Said to be Poland’s national dish, *bigos*—hunter’s stew—has ancient origins. It was first made of vegetables such as cabbage (fresh or as sauerkraut), mushrooms, and onions, along with prunes or apples and leftover game. It was a staple for hunters and was reheated frequently over outdoor fires. Some say a poorly made *bigos* will improve with reheating due to the condensation of flavors, but that a well-made *bigos* is delicious the first day. The meat used may be fresh pork or ham, sausages, poultry—goose or duck are considered best—and any game available. Madiera wine may be added as flavoring. Over the years, *bigos* has assumed greater importance at Polish New Year’s Eve celebrations.

*Waterzooi* is a well-known Flemish stew of fish or chicken, vegetables, and white wine. It is associated with the city of Ghent in East Flanders, Belgium. Most food experts claim the original stew was prepared with fish. Whether fish or chicken, the stew contains cream and is thickened with egg yolk.

**Africa.** Stews are used in some cultures for dipping bread or a type of porridge. The mainstay of the Ethiopian diet is *injera*, a pancakelike bread made from the nutritious grain *tef*. Pieces of *injera* are broken off and used to scoop up stew. *Wat* is the usual name for an Ethiopian stew, frequently seasoned with *berbere*, a dried spice and herb mixture that can be made hot with peppers. Milder Ethiopian stews are called *alechos*. Although meats, fish, and chicken are all used in preparing *wats*, the stew is more likely to be vegetarian because of the many meatless fast days required in the Ethiopian orthodox religion. Legumes are therefore often used in these stews.

The main carbohydrate for Nigerians is *fufu*, a thick paste that may be made from cassava, plantain, or from a grain. Nigerian immigrants in the United States sometimes use Cream of Wheat cereal to make *fufu*. A diner will scoop up some *fufu* in his or her fingers, deftly roll

it into a ball, and then use that to dip up some stew. Nigerian stews are often vegetarian dishes, but they may contain meat, fish, or poultry, and are usually made hot with peppers.

Zambians use pounded millet for their starchy dipping porridge. As in many cultures, meat stews are frequently preferred, but vegetarian stews are more likely to be readily available.

**Asia.** The ancient Chinese cooked *keng*, meat and/or vegetable stews, in cauldrons. Ceramic, and later bronze, cauldrons have been found in archaeological digs; some of these cauldrons are thought to be eight thousand years old. In *The Food of China*, E. N. Anderson describes the Chinese process of preparing and cooking a stew as a gentle, subtle, and slow art. The cook typically worked with a set of well-seasoned sand pots (sand-tempered earthenware); now metal woks with lids are used for cooking stews.

*Tubu-tchigae*, or bean curd stew, is a Korean meal that remains nostalgically popular. The dish is made with firm bean curd, pork, garlic, ginger, soy sauce, sesame oil, and *kochujang* (a red pepper, soybean, and glutinous rice paste).

The Japanese *iri-dori*, a one-pot chicken stew seasoned with mirin, sugar, and soy sauce does not require the long cooking times generally needed if a young chicken is used. A variation on this stew uses fish in place of poultry.

Filipinos make *adobo* from pork, chicken, and perhaps shellfish or fin fish. Seasonings include garlic, vinegar, and soy sauce, providing the sour-cool-salty taste the Filipinos desire. Another favorite stew in the Philippines is *puchero*, the traditional Sunday dinner. It is prepared with chicken, beef, tomatoes, sweet potatoes, and garbanzos and sometimes is served with a sauce made from eggplant.

**South America.** Argentineans cook their beef stews with fruits, perhaps peaches, and sometimes chunks of corn-on-the-cob. These stews may be baked in a pumpkin or squash shell. Stews are also everyday fare in Bolivia, Paraguay, and Uruguay. One is more likely to find fish stews in Chile than in other South American nations because of that country's long coastline.

**North America.** Traditional Mexican cooking included many stews because the meat and poultry used in that location were often not tender and they required the long, moist cooking characteristic of stews. In spite of the improved quality of meat and poultry in modern times, stews have prevailed as a favorite food. One stew, *mancha manteles de cerdo*, is prepared with three varieties of red chilis and tomatoes.

Mexico's *pozole de lujo* is often described as a "luxurious" pork stew. The recipe calls for a pig's head and pig's feet, with pork loin, chicken, and hominy. Mexican

*caldos* (stews or soups) are traditionally served with tortillas.

First Nations in Canada and Native Americans in the United States made stews in birch bark containers or hollowed-out trees before Europeans introduced metal containers. Some tribes left a stew on the fire for hours; its members would then add gathered plants or hunted game as they returned to camp.

The culinary history of both Canada and the United States includes numerous examples of stews brought by European settlers. Beef stews have been the most popular recipes among this legacy.

On the Canadian prairies, chuck-wagon cooks made stews from less tender cuts of meat. In the Laurentian Mountains of Quebec, a stew would typically be placed inside a wood-stove oven; the fire was then allowed to die down. The stew cooked in the waning fire. Ontario Mennonites still prepare stews in iron kettles.

Stews have been important food for most of the world's people for thousands of years, and there is no indication that this will change any day soon. They are wonderful concoctions, savored for their flavorful combinations as well as their reminders of home and family.

**STIMULANTS.** Foods and drinks (and other substances) that stimulate the consumer to enhanced mental alertness, increased or prolonged physical activity, uninhibited conviviality, or fierce fighting are called “stimulants.” This definition is intentionally a narrow one. It excludes the great majority of nourishing foods, for example, because a nourishing meal in itself produces, alongside a feeling of well-being, somnolence (sleepiness) rather than alertness and activity. It also excludes substances such as cannabis and opium (both occasionally taken as foods) that depress mental and physical activity: these are sedatives, not stimulants. We must distinguish enhanced mental alertness from hallucination, the tendency to see what isn’t there; hallucinogens are, therefore, also excluded. Other exclusions include appetizers, which stimulate the appetite for food, and aphrodisiacs, which (to the extent that such foods really exist) stimulate sexual appetites and energies.

Using foods that have a stimulant effect provides ways of intentionally adjusting the body’s metabolism, which carries risks. There is a good reason why a nourishing meal produces sleepiness: after such a meal, the body is occupied with digestion. Postponing or interrupting that activity may produce digestive disturbance. In any case, increased alertness and physical activity will eventually be paid for in greater-than-usual exhaustion, and there may be other undesirable aftereffects. For example, it may be necessary to compensate for the aftereffects of stimulants by using them again. If the desired effect lessens after frequent use, increased quantities might be needed. In this way, regular use turns into dependence and addiction.

It is even more true of stimulants than of foods in general that their use is not independent of its social context, but no simple generalization is possible. Some of the foods discussed here are nearly always taken in company, as part of a social ritual. Some are nearly always taken as part of, or immediately before or after, a meal. Some, however, are customarily taken when one is not in company and not eating a meal; such habits may vary from one culture to another. External observers focusing on individual psychology may see the solitary use of stimulant foods as posing a personal, social, or criminal problem, while social use might be perceived as no problem

or as a different kind of problem. Furthermore, observers focusing on social groups will find users of these stimulant foods to be unexpectedly protective, even nationalistic, about the preferred means of preparing them, which may vary widely.

Stimulant foods have been identified, like nearly all other foods and like many thousands of medicinal plants, in the course of very long-term unrecorded experiments: each human community explores its environment, notes animals and plants that may be of use, finds ways to use them, sometimes begins to farm them, and to trade in them. The stimulant effects of these foods were discovered empirically, as were their associated side-effects and dangers. In the last two centuries, chemists and nutrition scientists have identified their active constituents, making possible for the first time a scientific explanation of their effects.

In general, stimulant foods and drinks are either taken in a neutral vehicle, such as hot water, or they are slowly extracted by chewing. Nonfood stimulants are often taken as smoke or snuff. These various methods all ensure gradual absorption with relatively little interference from other foods. Alcoholic drinks are unusual because they are frequently taken without admixture and often contain strong flavorings: however, water is the principal constituent of most alcoholic drinks, and more water is often added.

Most traditional cultures had one, or at the most two, familiar stimulants. Globalization has changed this, producing such effects as the worldwide fashion for coffee; the worldwide marketing of chocolate, instant coffee, and the “cola” drinks; and the complex social interplay between alternative stimulants of almost equal status, neatly symbolized by the ritual question at breakfast in a French hotel, “*Café? Thé? Chocolat?*” (Coffee? Tea? Hot chocolate?)

### Caffeine

Caffeine is among the commonest of stimulants worldwide. It is the chief active constituent in coffee and tea, which are familiar in practically every country, and in maté, guaraná, and cola nut, which are popular in South America and West Africa. It is present in smaller quantities in some other stimulant foods, including chocolate.

**Coffee.** Coffee consists of the roasted, ground beans of *Coffea arabica*. Native to Ethiopia, its use spread in late medieval times to Yemen; from there it rapidly became popular around the Mediterranean. Both Arabs and Europeans encouraged its further spread. Details of its use vary. Boiling water is added; commonly sugar is used as a flavoring, and sometimes milk or cream. Often coffee is drunk after meals, but it is also often taken between meals, both by groups as a social drink and by workers as a stimulant. Several substances have been used as coffee substitutes. Most of them had the advantages of being cheap and of tasting somewhat like coffee but the

TABLE 1

Traditional stimulants: Origin and spread				
	Usual botanical source	Active constituent	Spread and current use	Analogues and substitutes
<b>South America</b>				
maté	<i>Ilex paraguariensis</i>	caffeine	Argentina, Paraguay, Uruguay, and southeastern Brazil	yaupon ( <i>Ilex vomitoria</i> ), cassine ( <i>I. cassine</i> ), American holly ( <i>I. opaca</i> ), and other <i>Ilex</i> species provide stimulant and narcotic beverages, mainly in North America
guaraná	<i>Paullinia cupana</i>	caffeine	Brazil only	
coca	<i>Erythroxylum coca</i> , <i>E. novogranatense</i>	cocaine	Western South America only. The derivative, cocaine, is widely used as an illicit drug.	<i>Erythroxylum cataractum</i> , <i>E. fimbriatum</i> , <i>E. macrophyllum</i> used locally in South America
<b>Central/North America</b>				
chocolate	<i>Theobroma cacao</i>	theobromine, caffeine	Central America. Worldwide; spread began in 16th century	Pataxte ( <i>Theobroma bicolor</i> ) used locally in Central America
tobacco	<i>Nicotiana tabacum</i>	nicotine	Eastern North America. Worldwide; spread began in 16th century	Wild tobacco ( <i>Nicotiana rustica</i> ) used locally in North America and elsewhere
Mormon tea	<i>Ephedra nevadensis</i>	pseudoephedrine	Western North America only	
<b>West Africa</b>				
cola	<i>Cola nitida</i> , <i>C. acuminata</i>	caffeine, theobromine	West Africa. Now an ingredient in some soft drinks worldwide	
<b>East Africa/Arabia</b>				
khat	<i>Catha edulis</i>	cathinone	Southern Arabia and northeastern Africa only	
coffee	<i>Coffea arabica</i>	caffeine	Ethiopia, then Yemen. Worldwide; spread began in 15th century mainly in Europe; instant coffee ( <i>Coffea robusta</i> ) now worldwide	Chicory root ( <i>Cichorium intybus</i> ) and other coffee substitutes
<b>Western Asia</b>				
wine	<i>Vitis vinifera</i>	alcohol	Northwestern Iran or southern Caucasus. Worldwide; spread began in 3d millennium B.C.E.	Also made from other fruits and other sources of sugar
beer	<i>Hordeum sativum</i>	alcohol	Mesopotamia; perhaps developed independently elsewhere	Also made from other cereals
<b>South and East Asia</b>				
tea	<i>Camellia sinensis</i>	caffeine	Southern China. Worldwide; spread began c. 9th century	There are many herbal teas, often sedative or medicinal, less often stimulant
betel	<i>Areca catechu</i>	arecoline	South and Southeast Asia only	
kratom	<i>Mitragyna speciosa</i>	mitragynine	Thailand only	
<b>Australia</b>				
pituri	<i>Duboisia hopwoodii</i>	nicotine	Australia only	
<b>Oceania</b>				
kava	<i>Piper methysticum</i>	kavalactones	Oceania only	

disadvantage of containing little or no caffeine. These substitutes have now been overtaken in popularity by instant coffee, a soluble product manufactured from the beans of *Coffea robusta*, which does contain caffeine.

**Tea.** Tea is made from the dried leaves of *Camellia sinensis*, native to southern China. The use of tea was already spreading beyond China in the ninth century; like coffee, it became popular in Europe in the seventeenth century and its use then spread worldwide. Again, like coffee, details of its use vary. Boiling water is usually poured onto the leaves, which are then allowed to steep for a few minutes. The resulting liquid is much lighter

in flavor and color than coffee. Some add sugar to it; fewer, notably the British, add milk; some drink it iced. Tea is more often taken between meals than during meals; like coffee, it is used both as a social drink and by workers as a stimulant.

**Caffeine beverages in South America.** Maté, also called Paraguayan tea, is made by pouring boiling water onto the dried and roasted leaves of yerba maté (*Ilex paraguariensis*). Most of the leaves that are used come from wild trees gathered from the forests of southern South America. Maté is traditionally a social drink, made in a gourd or a silver pot and sucked through a shared straw or

Betel nut sheller, Sri Lanka, nineteenth century. Wrought iron. The sharp blade cracks open the nut while the pointed handles serve as nut picks. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

silver tube. It is drunk while still extremely hot, so added pleasure is provided by watching the reactions of unskillful foreigners who burn their lips and mouths while trying to drink it. It is usually taken without sugar, but sometimes orange zest is added as a flavoring. Maté is the national beverage of Argentina and Paraguay but has never spread beyond the region. The plant is a relative of European holly (*Ilex aquifolium*), whose leaves have occasionally been used to make a narcotic drink; more importantly, it is related to yaupon or Carolina tea (*Ilex vomitoria*) and other species that have been used to make stimulating and narcotic drinks by North Americans both before and after European settlement.

Guaraná (*Paullinia cupana*) is a tropical plant native to Brazil. Its seeds are traditionally roasted, pounded, and made into cakes called “Brazilian chocolate.” They have this name not because they can be eaten solid, like modern chocolate bars, but because in pre-Columbian Mexico travelers used to carry similar cakes of powdered cacao for use in making an instant chocolate drink. Like those, cakes of guaraná are traditionally crumbled into water by tired travelers in Brazil, making a stimulating drink particularly rich in caffeine. Guaraná is now also used as a flavoring for soda, candy, and liqueurs.

**Caffeine in Africa.** The cola nut, a rich source of caffeine, is the usual native stimulant of West and Central Africa. It might rather be called a seed, since eight or ten of them are found in each fruit of the trees *Cola nitida* and *C. acuminata*. These seeds are white, pink, or red: the white ones are said to be the best. They are customarily chewed before meals: they have a bitter flavor but, per-

haps as a result of this, foods and drinks taken afterwards seem sweet (water, taken after cola, tastes “like white wine and sugar,” according to one observer). Apart from this effect as an appetizer, cola nuts have a high reputation among their traditional users, as stimulant, digestive, and aphrodisiac. Alongside caffeine, they contain theobromine (as does chocolate) and kolanin, a heart stimulant. Cola nuts can also be ground into powder and mixed with water as a drink, and cola extract is used to flavor sodas and candies: the names of Coca-Cola and Pepsi-Cola allude to cola nuts, which may well be an ingredient in these products.

### Theobromine

Theobromine is the chief active ingredient in cacao beans, the seeds of the tropical tree *Theobroma cacao*. These beans, fermented, roasted, and ground, are the raw material for chocolate, the traditional stimulant of Mexico, familiar worldwide. In pre-Columbian civilizations, chocolate was used as a drink: the ground cacao was mixed into hot water, which was then poured from a height into the serving cup to produce the much-desired foam. Flavors (chili, vanilla, or others) and color (notably annatto) might be added. Popularized in Europe by the Spanish, chocolate became successively a sugary drink and a milky drink; many other flavorings were tried, including the cinnamon now favored in Mexico. Eventually (in the nineteenth century) chocolate was made into bars to be eaten solid, and in many countries this is now its most familiar form. In the Maya and Aztec civilizations, chocolate was a social drink, taken after dinner, serving as a stimulant (and, according to some, an aphrodisiac). Whole chocolate contains caffeine as well as theobromine, and it is also rich in cocoa butter, making it an extremely nourishing food and, therefore, unlikely to produce aftereffects such as exhaustion.

### Nicotine

Tobacco, the fermented leaf of *Nicotiana tabacum*, is usually smoked; in that form it cannot be classified as a food. It can be chewed, however. In Western cultures, chewed tobacco has been typical of sailors and other manual workers subjected to extreme weather conditions that make smoking difficult. Tobacco’s active ingredient, nicotine, a deadly poison in the pure state, acts as a stimulant when slowly absorbed.

In Australia, another plant, *Duboisia hopwoodii*, has leaves and flowers very rich in nicotine. Aborigines dry and grind the leaves, mix them with the ash of certain other plants, and roll them into balls, called “pituri,” for chewing. These are used by solitary workers and travelers as a stimulant to stave off tiredness and hunger; they are also exchanged as a sign of friendship. They are, or were, used by warrior groups in preparation for a battle. There is a definite advantage in chewing ash in pituri (and also with coca and betel nut), because alkalis in the ash detach the active stimulant substance, in this case

nicotine, from the plant acids, allowing it to be more rapidly absorbed. The use of ash in this way has developed, apparently independently, in Australia, southeastern Asia, and South America.

### Cocaine

Coca is the dried leaf of a plant species native to western South America, *Erythroxylum coca*, and of a second species, *E. novogranatense*, which developed under cultivation. Coca leaves were known as a stimulant to the pre-Columbian peoples of the Andean region, and continued to be used by them and their Spanish conquerors. Their use is extremely widespread in South America. As with the nicotine plants, the principal use of coca leaves has been as a stimulant for workers and travelers. The usual way is to take some leaves, mix them with the ash of burnt coca or another wood, roll the mixture into a ball, and chew it. Coca leaves, like chocolate, are really nourishing, a property that tends to reduce the severity of the exhaustion that usually follows the use of stimulants. The active constituent of coca leaves was isolated (and named cocaine) in 1860. When taken in the pure form, cocaine was found to be a useful medicinal drug but also highly addictive. It was among the first stimulants to arouse strong medical and governmental disapproval. In the early twentieth century, many countries made it illegal. The name of Coca-Cola alludes to coca, and the early recipe for the product contained cocaine, like other soft drinks of the period.

Some other species of genus *Erythroxylum* contain cocaine or similar compounds and are used as stimulants by various South American peoples: *E. cataractum* by the Cubeo of Colombia; *E. fimbriatum* and *E. macrophyllum* by the Bora and Huitoto of Peru.

### Other Stimulants

**Betel.** The commonest traditional stimulant of southern and southeastern Asia is betel. Like pituri and coca, betel is customarily made up as a chewing packet that includes ash. The active ingredient, arecoline, is contained in the areca nut or betel nut (the nut of the palm *Areca catechu*), which is cut into long narrow pieces and placed inside the packet along with a "lime" made from burnt coral and oyster shells. The packet is formed from a leaf of the betel pepper vine (*Piper betle*). In traditional households, the betel chews are made up each day from fresh supplies; as with pituri, it is a sign of friendship and hospitality to offer a chew to any visitor. The habitual chewing of betel eventually stains the mouth red and the teeth black. When it is first tried, betel can produce feelings of anxiety, excitement, and vertigo; to those who use it regularly, it is a mild stimulant.

**Khat.** Coffee, when it was introduced to Yemen from across the Red Sea, was not the country's first stimulant. That position belongs to khat (or qat), the leaf of *Catha edulis*. Khat is used in Yemen, Saudi Arabia, and a large

area of East Africa from Ethiopia and Somalia to Mozambique and South Africa. It had not spread outside the region until some Americans acquired the taste for it while they were in Somalia with United Nations troops during the early 1990s. Khat is often taken as a tea, made by pouring boiling water onto the dried or fresh leaves. Fresh leaves can also be chewed; in this form its effect is said to be stronger than coffee but not as strong as alcohol. When chewed, khat is often used socially because it enlivens conversation. The principal active constituent in khat is cathinone, now classified as an illegal drug in the United States; however, cathinone is only present in fresh leaves. The second active constituent, cathine, which is still present in the dried leaves, is an appetite suppressant.

A milder stimulant of the same general type is Mormon tea, the leaf of *Ephedra nevadensis*. These leaves contain the active ingredient pseudoephedrine, and are made into a tea with boiling water.

**Kava.** The root of the plant kava-kava, *Piper methysticum*, is the source of kava, a familiar stimulant used in Hawaii and other Pacific islands. The fresh root is chopped or ground and then soaked and squeezed in water to produce a milky, spicy liquid, which is traditionally served in half coconut shells. Kava is a social drink whose effect is to produce a condition physically resembling drunkenness, though with apparent clarity of mind. The principal active constituents are known as kavalactones.

**Kratom.** Kratom, a stimulant indigenous to Thailand and little known elsewhere, consists of the leaves of *Mitragyna speciosa*. These leaves can be smoked or made into a tea. The active constituent is mitragynine, which, like cocaine, is a stimulant at low doses but a narcotic at higher doses.

### Alcohol

Alcohol is an atypical stimulant because it is not naturally present in any fresh plant. It is produced from the fermentation by yeast of plant sugars. One starting point is a fruit juice. Grape juice makes wine; apple juice makes (hard) cider; pear juice makes perry. Several other fruits are used in various parts of the world. A second starting point is malted cereal: barley is the commonest choice, and the result is beer. Plant saps can be used if they contain sufficient sugar: liquid cane sugar is so used in India, while pulque, a Mexican alcoholic drink, is made from the sap of the maguey (*Agave atrovirens*). Finally, honey, mixed with water, can be used, and the result is mead (a beverage that figures importantly in the Old English epic *Beowulf*). There are two common adjustments to the process: adding cane or beet sugar to the original juice gives the yeast more raw material to work with, producing more alcohol; distilling the final product achieves much greater concentrations of alcohol, resulting in "hard liquor."

Wine and beer are both ancient inventions, going back to southwestern Asia several thousand years B.C.E.

But yeasts are naturally present in the air; therefore, alcoholic drinks might have been invented or discovered many times in human history; certainly, the origin of pulque is independent of those of wine and beer.

Alcoholic drinks have most generally, in traditional societies, been used as social drinks, and they have commonly been used in a ritualistic way as well. Their production is linked with the seasons (in general the required juices are available only when fruit is ripe, and the fermentation process takes time); therefore, by contrast with most other stimulants, the discovery of alcoholic drinks and the annual vintage (especially of wine) tend to be celebrated in major festivals. In many cultures, the ordinary, everyday consumption of alcohol follows precise rules, tending to ensure, for example, that everyone drinks equally. Both in the major festivals and in everyday social drinking, it is commonly the case that drunkenness is aimed at, at least to the extent of the loss of inhibitions, but sometimes going all the way to unconsciousness.

Like kava—and unlike many stimulants—alcohol tends to produce enhanced mental activity accompanied by physical incapacity. In traditional societies, travelers used coca, maté, guaraná, pituri, and other stimulants to keep them going; they would not use alcohol or kava till they had arrived. Likewise, coffee, tea, and some similar stimulants may enhance one's ability to drive safely, for a certain period, while kava and alcohol impair it.

**STORAGE OF FOOD.** Civilizations are built upon a stable and reliable source of food that is provided by a combination of current production, imports, and the preservation of seasonally abundant crops. Preagricultural, nomadic people followed herds of migrating animals or periodically visited traditional locations to slaughter animals and gather fruits, vegetables, and grains as they matured during the year. Locally cultivated crops became the predominant source of food once agriculture became established and farmers tilled specific plots of land. Food that was locally abundant for only a short period of time had to be stored against times of scarcity. A poor harvest or the appropriation of food by marauding brigands could produce local famine. However, the most common and recurring cause of famine resulted from the farmer's inability to store enough food to last from one harvest to another. Summer was often not an idyllic time of plenty for primitive agrarian societies, but a time when many went hungry. It is not surprising then that the fall harvest festivals were such joyous times, for they heralded the end of the seasonal famine and ushered in a time of plenty.

Primitive storage techniques were well developed in prehistoric times. Early storage methods included the selection and growth of naturally dormant crops, and the drying, parching, smoking, and salting of meats, fruits, and vegetables. Mature grains, nuts, roots, and tubers have a period after harvest when they do not sprout and can easily be stored with the simplest of technologies and protective structures. Many cultivars of temperate fruits and vegetables such as apples, pears, and cabbage were selected for their natural storability. More perishable foods (meat, fruits, and vegetables) were sliced into thin sections and dried and/or smoked, or pickled in brine. Some of these techniques, such as sun drying (e.g., raisins), smoking (e.g., ham, fish), and pickling (e.g., dill pickle, pickled pig's feet) are still used today. The storage of food became more sophisticated as the population increased and more concentrated as demand for fresh fruits and vegetables increased. Storage was also used to provide planting materials or propagules for the next season.

The growth of large urban centers and the establishment of large standing armies at the end of the eighteenth century provided an impetus for the development of better storage methods. Canning was developed in 1809 in response to a competition sponsored by Napoleon to provide a better supply of food for his armies. A

tin-plated metal canister (from which the term “can” is derived) was filled and a lid hand-soldered in place after the can was heated in a water bath for a specified time. Canned food has a very long storage life, especially when stored under low temperatures. Food in century-old cans that were discovered at an arctic base was not spoiled, although it did contain viable bacteria and was unappetizing as a result of flavor and textural changes. Like canning, many storage technologies such as fermentation remained an unpredictable art until Pasteur identified microorganisms as the scientific cause of spoilage and decay in the 1860s.

With the Industrial Revolution, storage became increasingly important as the population increased dramatically and people moved into dense urban areas. As an affluent middle class developed, commodities that had once been luxuries available only to the nobility became widely available because of increasingly better storage and transportation technologies. For example, meat from Australia and Argentina appeared in European butcher shops, while tropical fruit such as bananas, citrus, and pineapples became available in grocery stores. Increased concern for a healthy diet and a better understanding of the link between diet and health prompted public demand for higher quality food.

Food quality encompasses a remarkable number of attributes. Although all food is made up of the same elementary constituents (carbon, hydrogen, oxygen, nitrogen, potassium, sulfur, etc.), the atoms it contains are arranged into molecules of diverse size, shape, and function. The idea that foods differed in molecular structure developed in the 1830s as food was found to contain the three major components of carbohydrates, proteins, and fats. Since then, more discovery of minerals, vitamins, and amino acids has increased to more than fifty, the essential nutrients found in food. Animals are incapable of many of the elementary syntheses performed by plants and therefore rely on them for many complex molecules such as vitamin C and the twenty-four essential amino acids. Many foods are consumed because of their pleasant aroma, taste, or texture, others because of their presumed medicinal properties. Storage technologies are devised and selected to preserve those specific characteristics that are most important to the consumer.

### Limits to Storage Life

The storage life of food is usually limited by the loss of acceptable visual appearance, palatability, or food value, and these criteria of quality are often lost in the reverse order listed. Food provides both nutrition and quality to our diet. Often a commodity can be physically preserved longer than the traits for which it is being stored. For example, the flavor, texture, and nutrition of many fruits and vegetables are reduced before visual appearance of spoilage. Many storage technologies have been devised to retain an acceptable appearance or taste while ignoring changes in food value. This is understandable since

TABLE 1

#### Useful storage life of plant and animal foods

Food produce	Storage life (Days at 59° F [15° C])
Meat, fish, poultry	1 - 2
Leafy vegetables	1 - 5
Fruits	2 - 20
Root crops	7 - 90
Dried, salted, smoked meat or fish	>360
Dried fruit	>360
Grain and dried seeds	>360

appearance and palatability can be easily assayed by examining and eating the commodity, while measuring food value requires sophisticated laboratory assays.

Food spoilage results from three main causes: chemical changes from ripening and senescence processes, growth of unwanted microorganisms such as bacteria and fungi, and insect and rodent pests. However, many of the processes that cause food spoilage in one commodity are often necessary for high quality in another. Ripening of bananas and tomatoes harvested at a mature but unripe stage is necessary, but excessive ripening leads to poor quality. Insects are needed for the pollination of many crops, but they can also eat the plant and spread disease. Microorganisms cause spoilage, but yeast ferment wine, beer, and sauerkraut, while bacteria are needed for production of pickles and yogurt.

Often more than one series of reactions affects storage life. For example, the major factor influencing the storage life of fresh meat is microbial growth and fat oxidation. Meat is normally marketed after *rigor mortis* and a period of aging. The most common preservation methods for fresh meat are cooling (three to six weeks at 32°F [0°C]) and freezing (nine to fifteen months at -4°F [-20°C]). Fish is far more perishable than meat because it is an excellent substrate for microbial growth. Fish lipids are largely unsaturated and therefore very susceptible to oxidation.

**Chemical deterioration.** Many chemical reactions contribute to the loss of storage life. The majority are enzymatically driven while others are chemical reactions that occur because of the close proximity of reactive molecules within food. Maillard browning involves color, flavor, and odor changes that result from a chemical reaction between proteins and carbohydrates. The rate of this spontaneous reaction is rapid at baking temperatures, as in the browning of bread, much slower at room temperature, as in the browning of applesauce, and very slow at refrigerator temperatures. Removal of water during dehydration concentrates the reactants and accelerates Maillard browning.

Hydrolysis is the splitting of molecules, usually polysaccharides such as complex sugars, starches, and pectins

with the chemical addition of water. During the processing of some fruits, the hydrolysis of sucrose into its components of glucose and fructose greatly affects the sweetness of the product. Storage of potatoes at too cold a temperature (32°F; 0°C) promotes the hydrolysis of starch to sugar. Sugars accumulating during this “sweetening” process turn dark brown when heated (i.e., Maillard browning), making the potatoes unsuited for the production of potato chips and French fries. Modification of amylopectins by hydrolysis contributes to textural changes and the formation of gels.

Oxidative rancidity is a chemical change in the unsaturated bonds of a fat or oil that produces chemicals giving food off-odors and off-flavors. Exclusion of oxygen and light combined with the addition of antioxidants retards rancidity. Vitamins C and E, which are antioxidants, can be destroyed by oxidation. Vitamin C, or ascorbic acid, is used as a reducing agent to prevent oxidative browning of cut fruits and vegetables. Both enzymatic and nonenzymatic reactions contribute to lipid oxidation. Blanching destroys enzymes responsible for rancidity reactions in fruits and vegetables. One of the functions of packaging is to exclude oxygen and light from processed foods. Cooked meats can become rancid within a day, but proper packaging or freezing can delay the process by several months. However, not all oxidation is detrimental; oxidative bleaching of pigments in flour during storage results in whiter flour.

**Microbial contamination.** Bacteria and fungus are everywhere in our environment, and most foods provide an excellent substrate for their growth. Packaging, whether natural (banana peel, seed coat, or egg shell) or artificial (glass bottle, metal can, or foil pouch) protects the enclosed food from microbial contamination. Some foods contain natural antimicrobial chemicals (for example, the tannins in unripe fruit), while other antimicrobial compounds, such as the fungicide in wax coatings, can be applied to food. Many foods are sterilized, pasteurized, or fumigated before packaging and storage to control microbes. Storage conditions of low temperature and humidity retard microbial growth. However, once these protective barriers are breached, microbial growth is often unchecked and rapidly destroys the commodity.

Food can be a vector and provide a growth medium for many pathogenic microbes (e.g., *Campylobacter jejuni*, *Escherichia coli*, *Listeria monocytogenes*, *Salmonella*, *Shigella*, *Vibrio cholerae*). However, common spoilage organisms (e.g., *Botrytis*, *Colletotrichum*, *Erwinia*, *Fusarium*, *Penicillium*, *Rhizopus*) are not human pathogens, although some bacteria (e.g., *Clostridium botulinum*, *Staphylococcus aureus*) and fungi (e.g., *Aspergillus flavus*) can produce potent toxins.

**Insect and rodent pests.** The major insect pests in stored food are moth (Lepidoptera) larva and beetle (Coleoptera) larva and adults. Insects have been controlled in stored food using physical methods for thousands of

years. Neolithic farmers in the Nile Delta kept seeds cool and dry by storing them in clay jars buried in the ground. Exposure to high temperatures has been used since the sixteenth century to control insects in stored grain. Under many circumstances the easiest, most rapid, and most economical method of controlling insects is with insecticides, often in the form of fumigants. Fumigation has been the method of choice since the late 1940s, but the unwanted side effects of some of the chemicals used (for example, toxicity to other species, depletion of stratospheric ozone, acquired resistance by the pest) have promoted interest in physical control measures. Many physical conditions such as temperature, relative humidity, moisture content, and atmospheric composition can be manipulated to affect insect survival. The structure containing the commodity (granaries, elevators, bags, and packaging), forces on the commodity (compression and impaction), and irradiation are also used in controlling insect infestation.

In general, insect survival in stored food is dependent on temperature, relative humidity, and gas composition. Temperatures lower than 55°F (13°C) or higher than 95°F (35°C) dramatically reduce survival. Sublethal temperatures also have effects; for example, at 68°F (20°C), most insects survive but stop feeding. Additional reductions in survival occur when stressful temperatures are combined with reduced moisture or oxygen levels. Drying affects insect population directly by reducing survival and indirectly by causing cracks that increase the susceptibility of the commodity to insect attack. The respiration by large numbers of insects produces heat and moisture, favoring both mold and further insect growth.

Physical movement of grain increases insect mortality. Moving grain by auger or pneumatic conveyer increases mortality of larva and adults. Impacts from dropping grain six meters resulted in up to 90 percent mortality. Moving can directly kill or injure insects by crushing them, or it can prevent feeding and mating by disrupting the microecological niches required by some insects. However, handling can also increase the amount of cracked seeds and grain dust, which are the preferred diet of some insects.

Biological control with insect pathogens, predators, or parasites is an important component of integrated pest management strategies. Unlike other treatments, biological control agents can reproduce, so one inoculation may be sufficient to establish lasting control. In contrast, many physical treatments such as cold, heat, fumigation, and irradiation have no lasting effect, and reinfestation must be controlled by proper storage and packaging.

Over the centuries, feral rodents have adapted to living in or near houses and farms. The most common rodents are the brown or Norway rat (*Rattus norvegicus*), the black rat (*Rattus rattus*), and the house mouse (*Mus musculus*). Food storage facilities provide ideal conditions for rodents to multiply very rapidly with food, shelter, and a

lack of predators. Common signs of a rodent problem are fecal droppings, tail and footprints in dust, droppings and urine stains in feeding areas, gnawing marks on wood, plastic, metal, pipes, and food containers, spilled food, smear marks from rodents' fur (distinctive dirty marks, particularly along skirting boards and around doors), rat holes, nesting sites, rat runs, and the rodents themselves. Constant gnawing is necessary to keep rats' teeth ground down; their gnawing of electrical wires has caused structural fires.

Rodents eat a lot of food, particularly in grain stores, but far more food has to be discarded because it has been contaminated with hairs and droppings. Apart from *salmonella* food poisoning, rats may carry as many as thirty-five diseases including rabies, plague, typhus, leptospirosis, rat bite fever, and hantavirus. Disease may be spread by eating food contaminated by rodent droppings or urine, contact with rat urine, parasites that live on rodents, and rodent bites.

There are biological factors, behavioral factors, and environmental factors to be considered in designing a rodent control program. Rats normally range no more than 150 feet from the nest; a male mouse will control an area of ten to twenty feet from the nest. Rats will migrate on their own; mice are often carried in boxes or crates into new locations. Rodents begin reproducing at a very young age, have large litters, and breed year around. A 90 percent population reduction may be replaced in as little as nine months. Rodents have a well-developed sense of taste and can remember foods that made them sick in the past. They are very cautious and wary of new objects introduced into their surroundings (such as bait boxes or traps) and of changes in the surroundings. Rodents can be controlled by using poisons and traps. Positioning of control measures can be optimized by using tracking powder to locate runs and nesting areas.

## Storage Technologies

Storage technologies manipulate the extrinsic factors of temperature, water activity, and oxygen availability to control the rate of quality loss by stored commodities. Examples of these treatments include drying, salting, brining, fermentation, canning, cooling, freezing, altering storage gases, and ionizing radiation.

**Temperature.** Temperature is the key factor influencing the storage life and safety of fresh and processed food. Living organisms are best adapted to a narrow range of temperature. As the temperature diverges from this optimum range, the organism is first retarded in growth and then killed (Table 2). Most of the physiological changes that shorten the storage life of fruits and vegetables, as well as many of the reactions in meat, eggs, and dairy products, are enzymatic. Other reactions are purely chemical. The effect of temperature is usually much greater for enzymatically driven reactions than for purely chemical reactions. Each 50°F (10°C) drop in tempera-

TABLE 2

### Response of insects that are found in stored product to temperature

Area	Temperature		Effect
	°F	°C	
Lethal	140 to 122	60 to 50	Death in minutes
	122 to 113	50 to 45	Death in hours
Sub-optimal	113 to 95	45 to 35	Development stops
	95 to 91	35 to 33	Development slows
Optimal	91 to 77	33 to 25	Maximum development
Sub-optimal	77 to 68	25 to 20	Development slows
	68 to 50	20 to 10	Development stops
Lethal	50 to 41	10 to 5	Death in days (un-acclimated)
	41 to 14	5 to -10	Death in weeks to months (acclimated)
	14 to -13	-10 to -25	Death in minutes

SOURCE: Modified from Fields and Muir, 1996.

ture halves the rate of most chemical reactions (i.e., a  $Q_{10}$  or temperature quotient of 2). In contrast, biological reactions often have  $Q_{10}$  values between 3 and 5, meaning that the reaction is decreased to a third or fifth by an 18°F (10°C) fall in temperature.

**Thermal processing.** Food is not stored at elevated temperatures, but high temperatures such as those involved in canning and pasteurization are often used to arrest microbial growth, denature enzymes, and alter the structure of food prior to storage. Temperatures above 140°F (60°C) inhibit and kill growing microorganisms. Reresting stages require much higher temperatures.

**Canning** is the heating of prepared food in hermetically sealed metal, glass, or foil containers to a specific temperature for a specified time to destroy disease-causing microorganisms, denature enzymes, and prevent spoilage. Low-acid foods such as meats and vegetables are heated to 240–265°F (116–129°C), while acidic foods, such as fruits and tomatoes, are heated to about 212°F (100°C). The length of heating depends on the type and size of the container, the food being canned, and the method of heating. Flat foil packets may require less than ten minutes, while large metal containers may require over forty minutes. The aseptic container keeps out oxygen and contaminating microorganisms. Canned food is very stable and can be stored for many months at ambient temperatures; however, storage life is extended when the food is stored at low temperatures. Once opened, canned food is prone to spoil rapidly and should be stored under refrigeration.

**Pasteurization** is the heating of a liquid such as milk, wine, or beer to between 131 and 158°F (55 and 70°C), to destroy harmful bacteria without substantially altering the liquid's composition, flavor, or nutritive value. In addition to destroying potential disease-causing bacteria,

pasteurization can greatly increase the storage life of milk by inactivating enzymes that reduce quality. There are two basic methods of pasteurization, batch or continuous. In the batch method a vat of liquid is heated to 145°F (63°C) for thirty minutes, rapidly cooled, and stored below 50°F (10°C). This method is used for milk and its by-products (e.g. creams, chocolate). Beer and wine are pasteurized at about 140°F (60°C) for twenty minutes. Water can also be pasteurized at 149°F (65°C) for six minutes, or to a higher temperature for a shorter time, to kill germs, viruses, and parasites. In contrast, the most common continuous processing method uses high temperature, short time (HTST) pasteurization. Milk is heated to 161°F (72°C) for fifteen seconds, while beer and wine are heated to 158°F (70°C) for about thirty seconds, and bottled under sterile conditions. The continuous process has several advantages over the vat method, the most important being time and energy saving. Radiation pasteurization of foods uses low doses of gamma rays, X-rays, and electrons to control foodborne pathogens on beef, pork, lamb, and fish.

**Refrigerated storage.** *Cold storage.* Most food stores best at temperatures near 32°F (0°C) because chemical and biological processes are slowed down. Maximum storage life for meat, eggs, dairy products, and all processed food is at 32°F (0°C). Most fresh fruits and vegetables are also best stored at 32°F (0°C). They include apples, berries, broccoli, cabbage, carrot, corn, grapes, lettuce, and pears. However, some fruits and vegetables are sensitive to low temperatures and are damaged if stored below 50°F (10°C). These chilling-sensitive commodities include asparagus, avocado, banana, beans, cucumber, eggplant, grapefruit, melons, peppers, potatoes, squash, sweet potato, tomato, and watermelon.

Best product quality is maintained under constant temperatures. Typically the storage temperature should vary no more than  $\pm 1.8^\circ\text{F}$  (1°C) from the desired temperature, but even this variability may be excessive if it allows the temperature to fall below the freezing point of the commodity. Large swings in temperature can result in unwanted freezing or chilling injury, condensation of water on the product that promotes microbial growth, accelerated water loss, and reduced storage life. All fresh fruits and vegetables lose water in storage and must be properly packaged and/or stored under high relative humidity to prevent excessive water and weight loss.

**Freezing.** Living cells are mainly dilute aqueous solutions of salts, sugars, organic acids, proteins, and lipids. These solutes lower the freezing point of pure water from 32°F (0°C) to 31.6°F (−0.2°C) for lettuce, 30.6°F (−0.8°C) for bananas, 29.5°F (−1.4°C) for carrots and sweet potatoes, 26.6°F (−3°C) for beef, fish and poultry, and 17.6°F (−8°C) for peanuts. Most frozen foods can be kept at 0°F (−18°C) for a year with little loss of quality. Both free and bound water exist in foods. Bound water exists in combination within an insoluble matrix such as cellulosic cell walls and muscle protein. As the tem-

perature falls, ice crystals first form where the water is the purest and therefore has the highest freezing point. Growing ice crystals remove pure water from the solution, and it becomes more concentrated. Slow freezing produces large ice crystals and highly concentrated solutions, both of which are detrimental to quality retention. Rapid freezing retains quality by either producing small ice crystals or a vitrified solid. The differential effects of freezing on bound and free water give rise to the complex freezing pattern of foods.

**Water activity and humidity.** Drying is perhaps the oldest method used to store food. Drying fish, meat, fruits, and vegetables in the sun or over a fire or by ventilation with heated air is still used to prolong storage life. Both the harvested food and the spoilage organism (microbe or insect) need water to live. Removal of water by drying, brining, salting, cooling, or freezing prevents the growth of microorganisms and insects, deactivates enzymatic pathways, and reduces the many chemical reactions that accompany a reduction in quality during storage.

Different foods can have different equilibrium moisture contents under the same relative humidity and different microbial stability under the same moisture content. The idea of water activity ( $a_w$ ) was introduced to better understand how water availability in foods affects microbes. The water activity ( $a_w$ ) of pure water is 1.00. The  $a_w$  of an aqueous solution is calculated by dividing the vapor pressure of solution by the vapor pressure of water at a given temperature. Under steady state conditions, water activity in food can be approximated by dividing the relative humidity of the ambient air by 100.

Few spoilage and pathogenic bacteria can grow below  $a_w$ 's of 0.90, while levels below 0.70 prevent the growth of most yeasts and molds. An  $a_w$  that influences microbial growth is usually lethal to grain, fruits, and vegetables. Food quality can still deteriorate at  $a_w$ 's below 0.60 from the enzymatic and nonenzymatic oxidation of lipids, vitamins, and pigments.

For most fresh fruits and vegetables, a relative humidity of 90 to 95 percent is recommended during storage. A relative humidity close to 100 percent or the condensation of water on a commodity that frequently accompanies such high humidity may cause cracking of the skin. Surface condensation may also accelerate the growth and spread of microorganisms. Large evaporator surfaces will improve the relative humidity in direct expansion refrigeration systems. A 41 to 50°F (5 to 10°C) temperature split, as commonly designed, will maintain 70 percent to 80 percent relative humidity; a 32.9°F (0.5°C) split would be required to maintain 95 percent relative humidity. In practice, supplementary humidification with fogging nozzles, spinning disc humidifiers, or steam humidifiers is often used to maintain high humidity in the storage of fruits and vegetables.

Dry cereal grains have an extremely low respiration rate and show only slight reduction in total sugars and

## METHODS USED TO STORE FOOD

### *Natural methods*

- Harvest as needed (field storage)
  - Slaughter animals as needed
  - Keep plants in the ground (carrots, cassava)
  - Keep fruit on the tree (avocados, citrus)
- Harvest and keep alive
  - Selection of naturally dormant plants (grains, nuts, bulbs, tubers)
  - Store in field or natural (clamps, curing, root cellars)

### *Technological methods*

- |                        |                       |
|------------------------|-----------------------|
| Harvest and keep alive |                       |
| Cold storage           | Controlled atmosphere |
| Curing                 | Ionizing radiation    |
| Harvest and process    |                       |
| Additives              | Aseptic packaging     |
| Brining                | Canning               |
| Cold storage           | Controlled atmosphere |
| Curing                 | Drying                |
| Fermentation           | Freeze-drying         |
| Freezing               | Fumigation            |

| Refrigeration          |                       |

quality even after years at a cool temperature and low oxygen concentration. In general, grain in equilibrium with 30 percent and 50 percent relative humidity air has a moisture content of about 8 percent and 12 percent, respectively. Grain respiration is particularly affected by moisture, increasing as the water content of the seed rises above 14 percent. Respiration produces heat and water, both of which contribute to increased respiration and an accelerated loss of quality. Warm temperatures and higher humidity also facilitate the growth of insects and molds. The moisture requirement for the growth and reproduction of different insect species in grains varies from 8 percent to 12 percent.

Controlling the moisture content is extremely important in preventing spoilage. Grains (e.g., wheat, rye, oats, barley, soybeans, corn, and sorghum) must be dried to around 12 percent moisture for safe storage during warm weather. Most grains are dry enough to store when harvested. Artificial drying of grains that are harvested before they are dry enough can be accomplished in a few hours with heated forced air. Longer times are required using dry (>70 percent relative humidity) ambient air. Rice storages must have driers since rice is customarily harvested before it is dry enough for storage. Temperature differences and air movement within grain stored at the proper moisture level can redistribute moisture and cause local increases conducive to spoilage. Respiration of the grain and associated pests (e.g., mold and insects) produces water that promotes their growth. Periodic ventilation and turning can remove or redistribute moisture to maintain proper storage conditions.

**Low oxygen and/or high carbon dioxide.** Researchers in the 1920s showed that altered concentrations of oxygen and carbon dioxide in the storage atmosphere retarded the germination and growth of microorganisms on fruits, vegetables, and meat. Low oxygen and moderately elevated carbon dioxide atmospheres retard respiration and the synthesis and action of the plant hormone ethylene and extend the storage life of fruits and vegetables. High carbon dioxide levels are more effective in prolonging the storage of meat.

Modified atmospheres have many advantages for the storage of both living and processed food, but the long treatment period may be incompatible with the marketing system. If crops sensitive to ethylene are to be stored together with crops that produce large amounts of ethylene, then either periodic or continuous venting may be necessary to prevent deleterious concentrations of ethylene from accumulating.

**Fermentation.** Oxygen is necessary for respiratory metabolism. Exclusion of oxygen causes a shift from aerobic to anaerobic metabolism and the production of many fermentative products such as ethanol and lactic acid. Fermentation is an ancient, low technology method of preserving food. When Ch'in Shih Huang Ti was constructing the Great Wall of China in the third century

B.C.E., the laborers were given mixed fermented vegetables as part of their rations. Fermentation is a complicated anaerobic process in which naturally present bacteria hydrolyze sugars to organic acids (e.g., acetic acid) or ethanol. Salt may be added to the initial mix to draw water from the vegetables and encourage brine formation. Brine promotes the growth of desirable bacteria; acid (vinegar or acetic acid) may be added to rapidly lower the pH and discourage the growth of undesirable bacteria.

**Ionizing radiation.** Ionizing radiation from gamma rays or electron beams is a cost-effective method of preparing food for storage. Low-dose irradiation controls insect infestation of grain and flour (0.2 to 0.7 kGy), food-borne parasites (1 kGy), and inactivates non-spore forming pathogenic bacteria (3 to 5 kGy). Higher dosages (20 to 50 kGy) are required to inactivate enzymes, kill spores and sterilize products. Levels of 0.2 to 1.0 kGy are not immediately lethal, and irradiated insects can survive for several weeks, but they feed less and are usually infertile. Higher dosages cause immediate mortality, but they can also reduce vitamin content and alter textural properties of grains. There is no residual effect of irradiation, so reinfestation must be controlled by appropriate handling

Storage basket for potatoes and onions made of willow and cherry branches, France, twentieth century. French farmhouse pantries were often furnished with several baskets of this type in varying sizes, the smallest for garlics, shallots, and fingerling potatoes. Food was removed through the trough at the bottom. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

and packaging. Low doses inhibit sprouting of potatoes and onions, but higher doses stimulate wound responses in fresh fruits and vegetables that lead to reduced quality. Spices and vegetable seasoning are the products most commonly irradiated. Aseptically packaged irradiated meat can be stored without refrigeration for many months. The U.S. military has used irradiated food for a number of years. Consumers view irradiated food either as being adulterated or as being additionally protected against spoilage.

***Sanitation, fumigation, and quarantine treatments.*** Since the leading cause of food spoilage is pests such as insects, fungi, and bacteria, storage life can be extended by removing these organisms. Using acceptable cultural practices during production of the raw material and sanitation practices during harvest and preparation for storage significantly decreases the initial number of pests present in stored food. Since many pests increase rapidly under favorable storage conditions, a significant reduction in their initial number can greatly extend the storage life of a commodity before expensive control measures are needed. Once stored, there are only a few techniques available to eliminate pests already present in raw and processed food.

Some of the most important control measures are fumigation, heat treatments, and controlled atmospheres. The anaerobic storage of grains in airtight containers can reduce the need for chemical fumigation to control insects and mold and does not require the technical sophistication required for the safe application of toxic fumigants. The hermetic storage of living tissue such as grains, fruits or vegetables is a form of modified atmosphere storage that has been used for centuries. The respiration of the commodity creates an atmosphere rich in carbon dioxide and deficient in oxygen. Some of these fast-acting treatments can be used as quarantine treatments. Many production areas throughout the world contain pests that importing countries do not want introduced into their production areas. Increasing international trade in staples and exotic foods and the elimination of effective, commonly used fumigants (e.g., methyl bromide) are promoting the development of new quarantine treatments that are not only environmentally safe, but also fast-acting and effective on a wide range of commodities.

### **Methods of Storage**

Food can be stored alive (apples, cows, tomatoes, wheat), or dead (applesauce, beefsteak, spaghetti sauce, flour). Storage technologies must produce drastically different environments to effectively store these many kinds of food. Cereal grains store best at a relative humidity below 50 percent to reduce respiration, while fresh fruit and vegetables need humidity above 90 percent to prevent excessive weight loss. Some ripening fruits (bananas and tomatoes) are injured if stored below 10°C (50°F), while others (apples and pears) store best at 0°C (32°F). Carbon dioxide levels above 50 percent reduce the spoilage of meat, and exclusion of oxygen prevents rancidity of potato chips and nuts, but most fruits and vegetables will not tolerate oxygen levels below 2 percent or carbon dioxide above 3 percent. Although the word “storage” may conjure up images of large grain elevators, warehouses, and sophisticated refrigeration technology, there still exists a range of less sophisticated techniques that are widely used today.

***Storage before slaughter or harvest.*** Animals can be slaughtered as necessary where the climate is mild or protective structures exist, and where animal feed is available or can be stored. However, animal products (eggs and milk) may need to be collected periodically to maintain production.

For most perishable food, maturity occurs over a short period of time, and harvest must take place during that period. However, a range of crops can be left on the plant (or in the ground) for up to a few months. The storage of potatoes and other root crops in the ground and the storage of citrus and avocados on the tree are good examples of this. Storage on the plant overcomes the need for capital investment in storage facilities and delays exposure of the commodity to water and nutritional loss

encountered during storage. It also reduces the damage and disease inevitably associated with harvesting, handling, and storage. Problems include exposure of the commodities to environmental disasters (hail, frost, diseases, and sunburn), the cost of keeping the land idle (for field crops) or of reducing the following seasons' yield (for tree crops).

**Storage after slaughter or harvest.** Food can be stored after slaughter or harvest as fresh, still-living commodities (fresh fruits and vegetables), or as a processed, dead product (cured meat, canned tomatoes, etc.). Low humidity and temperature are two traditional means of facilitating the storage of naturally dormant crops such as grains (wheat, corn, and rice), bulbs (onions and garlic) and, roots and tubers (carrots, potatoes, and yams). The rates of the many chemical reactions that reduce quality are naturally suppressed in these crops. Using chemicals or treatments that interfere with those physiological processes that naturally terminate dormancy can lengthen the duration of storage.

**Common (unrefrigerated) storage.** One of the oldest methods of storage of perishables is the use of "clamps," which are basically piles of a commodity laid in the field and then covered with straw and soil to insulate and waterproof the clamp. This method is still in use for the storage of potatoes, turnips, parsnips, celeriac, rutabagas ("Swedes") and other "hard" vegetables. In large clamps, ventilation with chimneys and perforated channels through the stack are needed to remove the heat of respiration, and reduce the risk of anaerobiosis or CO<sub>2</sub> toxicity.

A step in sophistication above field clamps is storage in rooms dug into the ground, such as root cellars, and natural or man-made caves, and buildings that are often heavily insulated. Temperatures in caves and underground (1 m) are fairly stable at 10 to 15°C (50 to 59°F) throughout the year. They have the advantage of low maintenance costs, stable temperatures, and high relative humidity. These unrefrigerated stores are best suited for long-lived commodities like potatoes, onions, and winter squash. But these structures are only effective in climates where the ambient temperatures during the storage period are low enough to maintain product quality for a reasonable length of time. Old-fashioned storage of apples, cabbage, and pumpkins in root cellars is a good example of this type of storage. This technique is still used for potatoes, particularly those intended as propagation material.

Grain storage facilities come in a number of sizes and shapes: rectangular wood-framed bins; cylindrical prefabricated metal structures; flat, ground-level piles on concrete floors in warehouse-type buildings; and overhead bins above driveways. One of the most common storage and processing facilities is the granary or grain elevator; a tall (c. 30 meters tall) cylindrical building equipped with machinery for unloading, weighing, clean-

ing, mixing, storing, and loading grain. Livestock farms may have a number of small granaries to store feed grain at locations adjacent to feedlots. Every town in a grain producing area has an elevator to accumulate grain from farmers and store it for a short period of time while it is cleaned, conditioned, dried, and graded. Larger elevators are located at terminal grain markets and shipping centers where the grain is stored for use by millers or to await shipment. Grain arriving by truck, railroad car, or ship is unloaded and moved by auger, or belt, bucket, or pneumatic conveyor to an area above the cylindrical storage bins where it is cleaned and weighed. A number of bins can be built side-by-side to form facilities that can store millions of bushels of grain. Governments in some countries subsidize the long-term storage of grain to stabilize prices and protect against famine. In contrast to a granary or elevator that stores grain, a silo is any structure or container used for the storage of large masses of high-moisture forage or silage for animal feed.

Once processed, food is more physically stable than the original living material, but it is also a better source of nutrients to microbes. Processed food can be preserved for extended periods by a combination of aseptic packaging such as canning or bottling to exclude microbes and oxygen and moderate to low temperatures.

**Night air storage.** In warmer climates, a modification of common storage can be used if there is a substantial difference between day and night temperatures during the storage season. The technique used is termed "night air ventilation." The produce is placed in a common storage room, which is well-insulated and supplied with a ventilation system to enable air to be drawn into it and distributed through the produce during the coolest part of the night. This technique can be used to remove field heat and cool produce before refrigerated storage. It can also be used to maintain produce at the proper storage temperature when the nights are cold. In modern stores of this type, microprocessor technology can be used to regulate the ventilation system to optimize the storage environment.

**Refrigerated storage.** By far the largest proportions of fresh commodities are stored in insulated rooms provided with mechanical refrigeration. At low temperatures, the biological activity (and deterioration) of the product is dramatically slowed, and the growth rate (and sometimes the viability) of microorganisms is reduced, as is the rate of water loss.

Several methods are employed to provide cold storage in the absence of mechanical refrigeration. In some areas, cold well or lake water may be used. The air of the store may be cooled to near the water temperature with a good heat-exchange system. In cold climates, ice harvested from lakes and ponds during winter can be stored and used for summer refrigeration.

In areas where the relative humidity is low, an evaporative cooler may reduce the temperature of the air

sufficiently to be an economical source of refrigeration. In the western United States, for example, the mean wet bulb temperature in growing areas ranges from 8 to 21°C (46 to 79°F) during the harvest season. A well-designed evaporative cooling system will provide cooling air at one or two degrees above the wet bulb temperature. Chilling-sensitive commodities can be cooled very satisfactorily by this technique. An additional advantage is that the high relative humidity produced during cooling significantly reduces water loss from the commodity.

**Mechanical refrigeration.** Without a doubt, the invention of mechanical refrigeration in the 1850s and its commercial application starting around 1875 was crucial to the modern storage of perishable food. Mechanical refrigeration relies on the basic principle that substantial amounts of energy (i.e., heat) are absorbed during the vaporization of a liquid and released during the condensation of a gas. Using a mechanical pump, a gaseous refrigerant is compressed, cooled, liquefied, and stored in the receiver. When cooling is needed, the liquid refrigerant is allowed to enter the evaporator where it evaporates into a gas as it absorbs heat from the cold storage enclosure. Fans blow air warmed by the commodity over the cold evaporator coils where heat is transferred from the air to the refrigerant. Repeated cycles of condensation and evaporation of the refrigerant “pumps” heat from the cold storage enclosure. Ammonia was the first and most commonly used refrigerant for many years. The development of Freons has produced refrigerants that are less toxic to plants and humans but that are being reassessed for their environmental impact.

There are a number of different techniques for using mechanical refrigeration in the cold storage of food. In the direct expansion method, the evaporator coils are in the cooled space. This system is simple, but it results in low relative humidity. Special and expensive modifications are necessary to provide high humidity for the storage of fresh fruits and vegetables. However, low relative humidity is beneficial for the storage of some commodities such as grains and onions and for canned or packaged processed food.

**STYLING OF FOOD.** The styling of food, usually referred to as “food styling,” is the art of preparing food to be photographed or filmed. The preparation, or styling, involved can be as deceptively simple as shopping for the perfect apple or as extreme as re-creating an elaborate, twelve-course belle epoque dinner party for fourteen. The creation of appealing images of food is a complex process. Whether the food is to be photographed for packaging, an advertisement, a cookbook, or a magazine, or to be filmed as part of a television commercial, cooking show, or movie, the styling of the food is an integral part of the process.

#### The People Who Do It: Food Stylists

Generally, those who work in the field of food styling are known as “food stylists.” Since there is no formal training available for food styling, the particular skills and techniques required are usually learned while apprenticed to or assisting an established food stylist. While most people entering the field have a background in the culinary arts, additional skills that are invaluable include a knowledge of basic food chemistry, the principles of design, and the ability to improvise. Until the late twentieth century, courses on food styling were rarely offered, even at

Food styling is sometimes more complex than preparing a dish of food for the camera. In this instance, the subject is a model and an entire shopping cart full of food. Shot on a platform in a studio, the final image gave the impression that the shopper was walking through a store. Also note that in 1949, when this picture was taken, women dressed to go shopping, even for groceries. © Bettmann/CORBIS.

the top cooking schools. Where offered, these courses are primarily an introduction to the field.

While the term “home economist” is sometimes used, this is basically a holdover from the era when home economists on staff at women’s service magazines (such as *Good Housekeeping*, *Ladies’ Home Journal*, and *McCall’s*), and large food corporations were responsible for the styling of food. Curiously, home economist is the term frequently used in the film industry.

Today, very few companies and magazines have food stylists on staff. Food stylists usually work on a freelance basis. The photographer, director, or production company hires them as needed, sometimes choosing a stylist that specializes in a certain area such as ice cream, chocolate, fast food, or baked goods.

### Is The Styling of Food Necessary?

The need for food styling is a question that is often raised. The photographing or filming of food is very involved, and many techniques are employed to stabilize, sustain, and, if necessary, enhance the food to be photographed. Most important is that the food look as fresh and appetizing as possible until the image is captured on film, but

this process can take hours. During that time, the food needs to be kept “alive,” or replaced as often as needed, sometimes very often. For example, it is difficult to take a photograph of a barbecue grill with flames lapping up through an arrangement of jumbo shrimp, because the flames will char the food within minutes. The food might need to be replaced a dozen times and look identical each time so as not to affect the lighting or camera framing. Or to shoot a commercial that features a slice of pie with a piece being broken off by a fork, twenty takes with twenty perfect slices might be needed before the director gets the shot in which the crust looks flaky enough. Even a bowlful of salad greens demands a unique knowledge and set of skills to keep it looking crisp and moist. This knowledge and these skills are essential to successful food styling, and ensure that the process of capturing the needed image on film is efficient and cost-effective.

While there is a trend toward a more documentary style of photographing food that shuns food styling, this seemingly straightforward approach still involves many of the same considerations that go into typical food photography: props, lighting, camera angle. While food photographed straight out of the kitchen might have an inherent honesty about it, the end result is not always

attractive. Most consumers, and more importantly the clients, still expect to see images of appealing food.

### The Process and Techniques Involved

Each project a food stylist undertakes is unique and has its own set of demands. The approach the stylist takes in preparing the food—even the same food—varies greatly depending on how the image is to be seen and used.

But before the food is prepared, there are several preliminary steps involved. The stylist meets with the photographer/director, and sometimes the client, to discuss what will be shot. The appropriate recipes, layout, or storyboards are reviewed. And from this, the necessary food, material, and equipment are determined. While the stylist is responsible for the shopping and purchasing of the needed food, actual product to be used is usually sent by the client. Often the shopping involves locating out-of-season or difficult-to-find items. The stylist then confers with the prop stylist (the person responsible for providing the tableware, linens, flowers, etc.) to make sure the props selected are suitable.

The first step in the actual preparation of the food is to create a “stand-in.” The stand-in is a close approximation of the finished food, and gives the photographer/director the time needed to compose and light the shot without worrying about the food “dying” on the set. Another important reason for preparing a stand-in is that it allows the client to make recommendations the stylist can incorporate into the final, or “hero,” food.

The preparation of the hero food involves any number of specialized techniques food stylists have developed to deal with the demands of photographing food. The overriding concern of the stylist is to keep the food looking fresh and alive. Moisture is critical.

Depending on the food, moisture is retained (or replenished) by brushing or spraying the surface with water or a thin coat of vegetable oil, and keeping the food under cover until needed. This is probably the most basic technique employed by the food stylist. It not only creates the appearance of freshness but can also make the food look juicy or even hot, since it is often cold and undercooked when photographed. (Heat will cause the food to continue cooking, then wilt and appear dried out.) For instance, vegetables are undercooked and kept in cold water until needed to retain their color. Poultry and meats are also undercooked, or cooked at lower than normal temperatures, to prevent them from shriveling or shrinking. A finished, roasted look is then added to the surface by brushing on gravy coloring, or browning the surface with a blowtorch. For a grilled look, grill marks are branded onto the surface using red-hot skewers.

Stabilizing delicate foods is a common challenge. This can be as straightforward as using toothpicks, straight pins, or hairpins to hold things in place. Or it can simply be a matter of placing a thin piece of cardboard under a slice of cake, or even meatloaf, to keep it

from breaking. More complicated stabilizing techniques involve the use of thickening agents such as gelatin or food starches. These can be used to keep sauces in place, or a slice of pie from collapsing.

Foods that oxidize easily (such as cut fruit) are dipped in lemon juice. Commercial antioxidants are also used; they are especially good for keeping leafy greens crisp or preventing the surfaces of sliced meat from turning gray.

Occasionally, substitutes for the actual food are used. This is done when the technical requirements of the photography or filming make it difficult or even impossible to use the real thing. A model might be made of a candy bar or a piece of cereal. Sometimes ice cream is made out of a mixture of confectioner’s sugar, vegetable shortening, and corn syrup. Hair tonic might be used in place of milk in a bowl of cereal.

In short, these examples represent just some of the basics of what is involved in the styling of food. More than the mere ability to prepare an attractive plate of food, successful food styling is a demanding occupation that requires resourcefulness, skill, and artistry.

**SUGAR AND SWEETENERS.** There are many sugars and sweeteners. Sucrose—the sugar obtained chiefly from sugar cane and sugar beets (see “Sugar Crops and Natural Sweeteners”)—is the most important sweetener and the substance usually meant when people speak of sugar. In 2000, world consumption of cane and beet sugar marketed by industrial-scale processors reached almost 120 million metric tons (132 million short tons), in white quality terms, equivalent to roughly 20 kilograms (about 44 pounds) per inhabitant. In addition, upwards of 10 million metric tons of indigenous types of cane and palm sugar of different qualities—the product of small rural enterprises—were consumed, mainly in Asia and Latin America. Globally, sugar supplies around 9 percent of the total human dietary energy intake, as all but a small amount produced ends up in food and drink. At the coun-

try level, average annual per capita sugar consumption ranges from less than 5 kilograms to more than 60 kilograms, depending on economic factors—price, income, and availability—as well as national customs, habits, and tastes.

### Sucrose

Ordinary refined, or white, sugar is at least 99.7 percent sucrose and is one of the purest products in common use. Like other carbohydrates, it is a stored form of energy, providing nearly 4 kilocalories (slightly more than 16 kilojoules) per gram. In the eyes of some Western food writers, this makes sugar merely “empty calories.” If that were all there is to it, sugar would not play the dietary role it does. Without its sweetness and other functions, the fact that sugar generally tends to be one of the cheapest sources of dietary energy might not, by itself, enable it to compete against starchy foods—even if these did not, in addition to energy, provide other nutrients. What basically makes sugar a staple food is that it enhances the beverages and other foods in which it is ingested. Sugar cannot be consumed by itself in significant volume. Potatoes or rice can be eaten by the plateful with barely anything else; it is difficult to ingest a teaspoonful of granulated sugar without at least dissolving it in water. Even as a source of energy, sugar rides piggyback on whatever else we eat and drink. It can be consumed in large quantities because, while satisfying the innate human disposition for sweetness, it is sweet in a not very intense way, far less so than numerous other substances.

Nowadays, global sugar consumption grows roughly in line with the increase in world population. In high-income industrial countries, per capita usage tends to stagnate and even decline. In poorer and less developed countries, on the other hand, sugar remains, as a study at the beginning of the 1960s found, one of the first foods to respond to a rise in personal incomes, its chief appeal lying not in its function as a source of energy—often still expensive, compared with locally grown cereals and root crops—but in its ability to make a frequently drab and monotonous diet more appetizing.

**Functional properties.** Sugar provides not only energy and sweetness. It caramelizes on heating to form complex coloring and flavoring substances, and part of it is inverted (converted by acid hydrolysis or enzyme into a mixture of glucose and fructose) during food preparation, the resultant monosaccharides reacting with other recipe components to lend aroma and browning to the final article. This increases the color, luster, and flavor of bread crust, for example. Well-known, too, is sugar’s antimicrobial effect—as in fruit preserves, marmalades, jellies, and jams—where the high concentration of sugar in solution inhibits the growth of spoilage microorganisms by raising the osmotic pressure.

In developed countries, the sugar used at home and in communal catering establishments represents only a minor portion of total consumption. German statistics

for 1999/2000, for instance, show 71.7 percent of total domestic sugar sales going directly to industry (principally food manufacturers), 22.9 percent to wholesale and retail traders, 0.2 percent straight to end users, and 5.2 percent to unknown recipients. Even in the United States, where sucrose has been widely replaced by high fructose syrup in food processing (especially in soft drinks, previously the largest single outlet), direct industrial receipts accounted for 58.5 percent of total sugar deliveries for human consumption in 2000. Producers of baked goods and cereals are now in first place among industrial sugar users, followed by makers of sweets and manufacturers of ice cream and dairy products. In addition to its nutritional value, sweetness, and other sensory functions (taste and aroma, texture and appearance), and preservative action, sugar fulfills the specific requirements of different food industries for a binder, bulking agent, fermentation substrate, or stabilizer. This does not exhaust the list of its functional properties, and the fact that sugar always acts in more than one way explains its wide use in food and beverages.

The many types and grades of sugar available in the marketplace reflect the multiple uses to which it is put in households and in industry. More than a dozen different kinds could be encountered in 2002 in a single British supermarket, for example: white beet or refined cane sugar—granulated, caster, icing, and cubes; unrefined cane sugar—golden granulated and caster, Demerara granulated and cubes, light and dark brown soft, light and dark muscovado, and molasses sugar; specialty items—amber sugar crystals, preserving sugar (large crystals), jam sugar (with pectin and citric acid), and a reduced-calorie mixture of sugar and the high-intensity synthetic sweeteners aspartame and acesulfame-K. Several kinds were available also in “organic” versions. One important distinction is the size of crystal. Finer sugar tends to dissolve more rapidly than coarser sugar. Also, the smaller the crystal, the greater the total surface area of crystals per unit of mass or volume. In raw and recoated white or refined sugars, each crystal is surrounded by a film of molasses or syrup containing nonsucrose substances that, while nutritionally insignificant, have technical and sensory effects such as taste. Therefore, the smaller the crystal, the greater the proportion of syrup or molasses in the product, a desirable characteristic in making things like dark fruitcake and gingerbread.

Still other types of sugar reflect national or regional processing technologies, customs, and tastes. So-called amorphous sugar features prominently in Brazil, as does white soft sugar in Japan. The loaves of the sugar bakers, which in their blue wrappers graced the shelves of nineteenth-century grocers’ shops before cubing processes were invented, live on in Germany, where they are required on festive occasions for the preparation of mulled wine. Loaf sugar also remains popular in North Africa and the Near East, a legacy attributed to the fact that the loaves were easy to transport hung from the backs

of camels. More importantly, altogether millions of tons of sugar, the product of boiling cane juice or the sap of palms in open pans, are still consumed, notably in the countries of the Indian subcontinent and Southeast Asia, China, and Colombia.

Granulated sugar going to processing industries is shipped in bulk or bagged in sacks, for the greater part directly from the factory or refinery, and often tailored to customers' specifications, especially concerning grain size. Many applications, however, require an aqueous solution. Dissolving batches of granulated sugar stands in the way of continuous manufacturing operations. Hence, beginning in the United States in the 1920s, large sugar users have increasingly obtained bulk delivery in liquid form. What is known generically as liquid sugar comes in many guises, in accordance with industry demands: colorless and colored; uninverted sucrose or partially or totally inverted (converted into glucose and fructose); unblended or mixed with glucose syrups and other components. Depending on type, liquid sugar contains 67 to 77 percent dry substance.

**Nutritional, health, and safety aspects.** Whether robbing wild bees of their honey, as did our ancestors, or extracting sucrose from sugar cane or sugar beets, humans take easily assimilable energy from the environment because we are heterotrophs or feeders on others and cannot fix carbon dioxide from the air. Instead, we have to obtain our carbon in a more elaborate form. Nutritionally, we utilize sugar, like other carbohydrates, as a fuel to obtain the energy to function. Under normal physiological conditions, sucrose must be enzymatically hydrolyzed in the small intestine before it can be absorbed across the intestinal wall. Glucose is the body's preferred fuel and the only one that powers the brain.

As a food, sugar is now subject to international and national standards and public health regulations, on top of the quality assurances and specifications of producers and industrial users. Compliance is underpinned by a large body of sensitive analytical methods.

The Codex Alimentarius, drawn up by a joint commission of the Food and Agriculture Organization and the World Health Organization of the United Nations, recommends international standards for white, powdered, and soft sugars, among other products. The basic white sugar standard lays down the minimum content of sucrose and the maximum contents of invert sugar, conductivity ash, sulfur dioxide (a processing aid), and the contaminants arsenic, copper, and lead. Binding regulations impose similar specifications across the European Union. The U.S. Food Chemical Codex is an example of controls at the national level. Since sucrose is used in pharmaceutical preparations as a binder, bulking agent, and taste corrective, it is also included in international and national lists of drugs and medicinal preparations.

Virtually a pure carbohydrate—even raw sugar supplies practically no minerals or vitamins, no fiber, and no

protein—sugar is widely attacked on nutritional and health grounds. The safety aspects of sugar and its impact on human health have been extensively examined by scientists and reviewed by expert committees such as the U.S. Food and Drug Administration (FDA) Sugars Task Force and the British Nutrition Foundation's Task Force on Sugars and Syrups. On the evidence, the consumption of sugar and other fermentable carbohydrates contributes significantly to the incidence of dental caries, which have multiple causes, however. Other than that, no conclusive proof has been found that dietary sugars pose a health hazard to the general public. They are not related to diabetes, except as a nonspecific energy source, nor to behavioral changes. They do not have a unique role as a cause of obesity or constitute an independent risk factor in cardiovascular disease, gallstones, cancer, or hypertension.

**History.** The word "sugar," like its cognates in many languages, comes ultimately from Sanskrit. Crystalline sugar has been made in northern India since the fifth century B.C.E., if not earlier. Sugar in solid form, possibly imported from Indochina, was also known in China by the third century C.E. To the west, however, the comparatively short move of the industry from India into Persia did not take place until c.600 C.E. From there, it rapidly diffused westward across the Middle East in the train of Arab expansion.

For the better part of 900 years between 700 and 1600, sugar production outside of Asia flourished on the islands and around the shores of the Mediterranean, with Venice initially the foremost center of refining and trading. The second half of the period saw the first exports to central and northern Europe, triggering what Sidney Mintz has called "the conquest of honey by sucrose," albeit that sugar was still a rare and expensive luxury, its use confined to kings and nobles. The Mediterranean industry began to decline from about 1450 onwards, in parallel with the appearance of more efficient producers in the new Portuguese and Spanish colonies in the eastern Atlantic and the Americas, although that was not the sole reason. For a while, Madeira, the Canaries, and São Tomé figured prominently in the burgeoning international sugar trade, forerunners of the West Indian "sugar colonies" and "sugar islands" that Adam Smith spoke of in his *Wealth of Nations*. But, like the Mediterranean industry, they, too, could not match the natural conditions and space for growing sugar cane that lay waiting in the Western Hemisphere.

When Christopher Columbus carried sugar cane to the Americas on his second voyage in 1493, shortly followed by other Spanish and Portuguese explorers with their cargoes, the seed was sown for a vast expansion of the industry. Within a few decades, supplies doubled and doubled again, prices fell, and consumption extended to the middle classes. Still, about a century and a half after sugar from Brazil and Hispaniola became the first example of profitable agricultural exports from the Western

Hemisphere, average per capita sugar consumption in Britain in the first decade of the 1700s is estimated to have amounted to just four pounds a year, less than two kilograms, or about a teaspoonful a day. On the other side of the Atlantic, the growth of the sugar industry had lasting political, economic, social, and cultural consequences: based on plantation agriculture and slavery on a scale many times greater than previously seen in the Old World, it was instrumental in the formation of new nations.

Until the early 1800s, cane sugar had the field to itself, leaving aside sweeteners of no more than regional significance. Honey was a competitor only so long as sugar was still a costly rarity. Even then, the two products complemented as much as competed with each other. All that changed with the arrival of beet sugar early in the nineteenth century, a historically significant event aptly described by Timoshenko and Swerling as “the earliest example of the market for an important tropical product being seriously eroded by the application of modern scientific methods in relatively advanced countries.” Extraordinarily, the challenge came not from a substitute but from what was, for all practical purposes, the identical substance, obtained from an entirely different plant. High-grade refined sugar from beet or cane is indistinguishable except by analytical methods that find the difference in the carbon isotope ratio ( $^{13}\text{C}/^{12}\text{C}$ ).

Beet sugar added another dimension to the world sugar economy. It allowed temperate zone countries to produce their own sucrose and greatly increased global availabilities, so that sugar could become a staple item of consumption for all classes of society. By 1880, Austria-Hungary, France, Germany, and Russia were turning out beet sugar on a scale comparable to the largest cane sugar producers. Europe’s beet sugar industries contributed enormously to its economic development in the second half of the nineteenth century. The Germany of the 1890s, for instance, had around 400 beet sugar factories, producing roughly one-and-a-half million metric tons of beet sugar a year, and sugar briefly headed the list of German merchandise exports. In his work *Der moderne Kapitalismus*, the German economist Werner Sombart wrote: “The sugar and distilling industries were the industrial sectors through which Germany developed into a great capitalist power, rather as the cotton and iron industries laid the basis for England’s greatness.”

Nowadays, most countries cover their requirements at least partially with homegrown sugar, and some that do not, such as New Zealand, possess a refinery to process raw sugar imports. The bulk of the world’s sugar is today consumed in the countries where it is produced. Not surprisingly, in view of its sundry roles, sugar has become deeply embedded in politics over the centuries, and how much is produced and where is heavily influenced by tariffs, taxation, and subsidies.

Several industry-specific factors have favored the growth of sugar production and consumption through-

out history. Sugar’s multiple functions, from its first uses as a medicine and condiment, have clearly been an advantage in boosting consumption. So was its long-time association in Europe with wealth and standing—demonstrated, for instance, by its conspicuous display in molded table decorations. In modern parlance, sugar enjoyed “snob appeal.” Economists would say that it had a high positive-income elasticity of demand and confirmed Say’s law that supply creates its own demand. Even as sugar becomes an inferior good in highly developed countries, consumption is sustained by increased demand for things like ice cream, sweets, and soft drinks, so long, of course, as these continue to be made with sugar and not other sweeteners.

On the production side, the by-products of sugar processing have always played a significant role in the viability of the industry. Sugar mills in many parts of tropical America survived deforestation and the scarcity of firewood because sugar cane brought its own fuel in the form of bagasse, the fibrous processing residue. Indeed, a modern raw cane sugar factory normally produces more bagasse or steam than it needs. The corresponding residue in the beet sugar industry—pulp—provides valuable fodder. Molasses, a by-product in both industries, is likewise utilized directly or in mixed feeds, or as a raw material for fermentation products. Students of U.S. history will be familiar with John Adams’s statement in 1775: “I know not why we should blush to confess that molasses was an essential ingredient in American independence. Many great events have proceeded from much smaller causes.”

The very nature of the industry facilitated its diffusion to and growth in new territories. A state-of-the-art sugar factory, operating at top technical efficiency, is an extremely sophisticated business—science-inspired, instrument-controlled, and automated. In essence, however, the methods of sugar processing are simple and robust. Although economies of scale have led to ever larger plants, sugar can be made in a wide range of plant sizes. The processes involved are easily scaled up, and factories can be enlarged and updated piecemeal by retrofitting new equipment. Right down to the present, the world cane sugar industry exhibits a technological diversity ranging from back-yard producers of a few tons of sugar, similar to that made centuries ago, to huge installations, pouring out hundreds of thousands of tons a year of high-grade product.

**Technology.** Sugar processing is basically a series of solid-liquid separations. The core processing stages are: (1) extraction of the juice, with bagasse or pulp the residue; (2) purification of the juice, removing non-sucrose substances; (3) concentration of the purified juice to syrup by evaporating water; (4) crystallization of the sucrose in the syrup by further evaporation; (5) separation of the crystals from the syrup. The methods employed after juice extraction determine the end product. One way leads to raw sugar, which is refined—on site or

in a separate plant—by washing and redissolving the crystals and further clarifying and decolorizing the resulting solution. The clear syrup is then again boiled until crystals form, or made into liquid sugar. Much of the world's cane sugar is produced in this way. The alternative is to make white sugar directly after complex purification of the juice, the procedure followed in some cane-sugar factories and throughout the beet-sugar industry.

For two thousand years, machinery, apparatus, and processes underwent a slow and gradual evolution, highlighted by the crucial seventeenth-century innovations of the three-roller mill and the battery of cauldrons, which, once fitted with a single furnace and continuous internal flue, became known as the Jamaica train and survives to this day among small-scale producers of open-pan sugars (not made in closed vessels under vacuum). Development accelerated with the introduction of steam and the rise of industrial chemistry in the nineteenth century. By about 1880 the basic tool kit of the sugar industry was virtually complete, and that date marks the beginning of the modern era in sugar production.

## Nonsucrose Sweeteners

**High fructose syrups (HFS) and other caloric sweeteners.** Sucrose substitutes fall into two categories: nutritive or caloric substances, which, like sucrose, provide energy and bulk, and high-intensity sweeteners, used principally for their sweetening power, although that is not their only property. The discovery of how to convert starch into sugar (saccharification) in 1811 was the first step toward the development of serious commercial competitors to cane and beet sugar of the first kind. Still, the glucose syrups produced over the next 150 years were less sweet than invert sugar syrup, which restricted their range of industrial applications. That limitation was lifted by the invention of isomerization processes leading to high-fructose syrup, known as high-fructose corn syrup in North America and isoglucose in Europe. While glucose syrups continued to be made, world HFS production rose in less than forty years from zero to an estimated 13.1 million tons, dry weight, in 2001/2002. The United States accounted for 73 percent of global output; another 18 percent was shared by Japan, the European Union, Turkey, South Korea, Canada, and Argentina, and the remainder by more than a dozen other countries.

Location and volume of HFS production are conditioned by several factors:

1. Price: World sugar price booms in 1963, 1974, and 1980 greatly stimulated development. In the United States and Japan, two large sugar importers, HFS progressed under the umbrella of protective sugar regimes that kept sugar prices at an artificial level and ensured that, however much HFS manufacturers undercut the price of sucrose, displacement of the latter reduced sugar imports and did not impair domestic sugar production;
2. Starch supply: Ample supplies of starch at a competitive cost, net of by-product proceeds;
3. Consumer demand: Sufficient sweetener consumption in the form of processed foods and beverages, and the existence of bulk-handling facilities for liquid products;
4. Money: Financial resources for investment in research and development as well as in capital-intensive plants and equipment;
5. Political climate: Supportive, or at least permissive, government policies; in the European Union, however, isoglucose manufacture—and, more recently, also that of insulin syrup—has been restrained, first by a levy, then by production quotas.

Besides syrups, starch saccharification leads to dextrose or crystallized glucose. Sold in anhydrous (at least 98 percent solids) or monohydrate (at least 90 percent solids) form, dextrose is used in food and other industries.

Also employed industrially as bulking, humectant (moisturizing), and texturizing agents and in diabetic foods are various sugar alcohols or polyols. These have lower calorific values than sucrose and, with the exception of xylitol, only about half the sweetening power. The main one, sorbitol, occurs naturally in many plants—as does its isomer, mannitol—and is used, among other things, to synthesize ascorbic acid (vitamin C). It is commercially obtained by the hydrogenation of glucose or of invert sugar, the latter yielding equimolar amounts of sorbitol and mannitol from the fructose and sorbitol only from the glucose. Other members of this class are maltitol, produced by hydrogenation from high-maltose syrup; isomalt, for which sucrose is the feedstock; xylitol, made from xylose-containing materials, such as corncobs and birchwood sawdust; and erythritol, found in lichens and made from glucose by fermentation.

**High-intensity sweeteners.** Artificial or natural substances with many times the sweetening power of sucrose, but no or negligible calorific value as used, are known as high-intensity sweeteners. Saccharin, the oldest of the kind, is about 300 times as sweet as sucrose. A derivative of the tar product toluene, it first achieved some market significance during the sugar shortages caused by World War I, when it began to be used as a substitute by people besides those who were unable to tolerate sugar. Newer sweeteners have, to a considerable extent, displaced saccharin, but it continues in demand, particularly in Asia, because it costs a small fraction of the price of sugar in terms of sweetness equivalence. Another older artificial sweetener, cyclamate, roughly thirty times as sweet as sugar, was discovered in 1937 and became popular after World War II, usually in combination with saccharin. Together, each masks the unsatisfactory taste of the other, producing an overall taste profile thought to approximate that of sugar.

Such blending of different sweeteners, nutritive as well as high-intensity, is a striking feature of sweetener

usage in processed foods and beverages. One advantage lies in the resultant synergism—the sweetness effect of the mixture is greater than the sum of the sweetening powers of the individual components, enabling manufacturers to save costs and label certain products “reduced calorie.” Blends may also produce other taste synergies and enhance the stability of the product.

The scope for blending was greatly increased in recent decades with the introduction of aspartame and acesulfame-K. Aspartame, a methylated amino acid dipeptide, actually has the same calorific value as sugar, but is about 180 times sweeter. Its taste profile closely resembles that of sucrose and, unlike saccharin, it has no bitter aftertaste. Widely used as a tabletop sweetener, aspartame is not suitable for all processed products because it can lose sweetness, depending on temperature, moisture, and degree of acidity. In contrast, acesulfame-K, the potassium salt of methyl oxathiazinone dioxide roughly 200 times as sweet as sugar, while more expensive, is very stable, blends well with other sweeteners, and is highly synergistic.

The latest artificial sweetener to acquire significant market presence is sucralose, which is 600 times sweeter than sugar. Technically trichloro-galactosaccharose, sucralose is actually made from sugar. It has the advantages of a good taste profile and of being acid and temperature stable. Several other substances, some with many thousand times the sweetness intensity of sugar, are waiting in the wings. High-intensity sweeteners are classified as food additives and require approval by national food safety authorities. Gaining approval tends to be a lengthy procedure and, once given, can be withdrawn. In the United States, for instance, cyclamate was banned in 1970, but it is allowed in many other countries.

## Summary

Sucrose remains the benchmark against which the quality and price of substitutes are judged, but it has lost its former virtual monopoly as the sweetener and conditioner of food and drink. Not all the growth of non-sucrose sweeteners has been at the expense of sugar. Some of it reflects the development of new products, such as diet soft drinks. In certain applications, sugar and other sweeteners have to be blended in order to achieve the desired texture and consistency. Moreover, nonsucrose sweeteners compete not only against sugar, but also among themselves: aspartame against saccharin, and diet soft drinks sweetened with high-intensity sweeteners against regular soft drinks sweetened with HFS. Only in the United States was sucrose no longer the dominant sweetener at the beginning of the twenty-first century. Globally, sucrose still accounted for 70 percent or more of world sweetener consumption.

G. B. Hagelberg

**SUGAR CROPS AND NATURAL SWEETENERS.** Chemically, the substance in the breakfast sugar bowl comes to us unchanged from the living organism in which it was manufactured. The familiar crystals are virtually pure sucrose, an organic chemical belonging to a large family of compounds classified as sugars. These, in turn, are members of a still larger group—the carbohydrates—that also includes starch and cellulose. The

breakdown of carbohydrates into monosaccharides, oligosaccharides, and polysaccharides points to the relationship.

Carbohydrates are a product of photosynthesis, the complex biochemical process whereby green plants use light energy to combine aerial carbon dioxide and hydrogen from soil water, forming rings of carbon atoms to which atoms of hydrogen and oxygen are attached, usually in the ratio in which these elements occur in water (hence the name), surplus oxygen being released as free gas. Stripped of all detail, the photosynthetic reaction that produces the basic monosaccharide glucose may be summarized by the equation:

### Affinities

Various carbohydrates are made in the course of photosynthesis. Sugars are the simplest. Glucose, also called dextrose and grape sugar, is the most prevalent sugar in nature. It occurs in the free state in fruits, plant juices and honey, as well as in blood. Polymerization of glucose leads to starch and cellulose—the one a form of energy storage, the other the main structural material of plants—both nothing but chains of glucose units. Conversely, natural starches can be saccharified by acid hydrolysis and enzymes to yield different types of sweet syrups or crystalline dextrose. Another monosaccharide, fructose (also called levulose and fruit sugar), occurs in the free state notably in honey. Sharing the same chemical formula but differing in structure, glucose and fructose are in fact interconvertible by chemical and biological reactions.

Fructose and glucose combine to form the oligosaccharide — more precisely, disaccharide — sucrose,  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ , shedding a molecule of water in the process. Sucrose is found in the sap of many plants and like starch functions as a storage product. It is easily hydrolyzed by acid or enzyme to equimolar amounts of glucose and fructose, and the mixture is then called invert sugar.

A family trait of many mono- and oligosaccharides is their sweet taste. Fruits, young vegetables, the nectar of flowers, and the sap of certain plants and trees taste sweet because they contain saccharides. Sucrose is generally used as the standard for relative sweetness, but this also depends on concentration, temperature and other factors affecting the physiology of taste. Approximate relative sweetness values for the sugars mentioned are:

Fructose	120	Invert sugar	95
Sucrose	100	Glucose	65

Sucrose, almost all of which is obtained from sugar cane and sugar beet, is commercially by far the most important sweetener. Its origin in photosynthesis explains how two wholly dissimilar botanical sources can furnish a practically identical product. Sugar cane—currently providing roughly three-quarters of the world's sucrose

supply—is a perennial monocotyledon, propagated from cuttings, except in the breeding of new varieties, and capable of giving repeated harvests. In contrast, sugar beet is a biennial dicotyledon, harvested in the first season and replanted annually from seed. Cane grows in the tropics and subtropics, beet in temperate climates. The cane's sucrose comes from the stalk, the beet's from its root. Sugar cane has been exploited industrially for more than two millennia, sugar beet for just two centuries.

The origin of sugars in photosynthesis also explains the exploitation of other, more or less important sweetener sources, some going back to ancient times, for example boiled-down grape juice, fig and date syrup, the sap of palms, the maple tree, and sweet sorghum, and the exudations from certain trees and shrubs. Like the sugar from cane and beet, honey—the first concentrated sweetener known to humans—is ultimately a product of photosynthesis. In essence, bees making honey and humans processing cane or beet to crystal sugar are doing the same thing—both extract dilute sugar solutions from plants and convert them into forms that are easier to handle and storable by evaporating unwanted water.

### Sugar Cane

**Physical characteristics.** Sugar cane is a giant perennial grass that tillers at the base to produce clumps of solid unbranched stems up to six centimeters in diameter and typically two to three meters long at maturity. It is grown for these thick stems which, stripped of tips and leaves, weigh between 500 and 2000 grams and, as a rule, contain 10–15 percent sucrose and 11–16 percent fiber. Each stem is divided into a number of joints comprising a node and an internode up to twenty-five centimeters in length. A node consists of a lateral bud in a leaf axil, a band containing root primordia, and a growth ring. Sword-shaped leaves, consisting of a sheath and a blade, are attached to the stem at the base of the nodes, alternating in two rows on opposite sides of the stem. The stems range in color from green or yellow to red, purple, violet, or striped, and have a hard wax-covered rind that reduces loss of water by evaporation. Depending on variety, plant age, and natural conditions, sugar cane may flower, producing plumelike panicles known as arrows or tassels that bear hundreds of small spikelets with inconspicuous flowerets. For sugar production, however, sugar cane is propagated vegetatively from stem cuttings or setts bearing at least one bud. Planted in moist soil, the bud develops into a primary stem, the basal buds of which form secondary stems, and so on, while rootlets sprout from the root primordia band on the sett. In time, the tillers throw out their own roots and, in favorable soil conditions, an established cane stool develops an elaborate root system of widely spreading superficial roots that absorb water and nutrients and buttress roots to provide stability, as well as a few vertical roots that may penetrate deep into the soil where moisture is available even during a severe drought.

**Origin and geographical spread.** All forms of sugar cane are species or hybrids of the genus *Saccharum*, a member of the large family of Gramineae in the tribe Andropogoneae, the sorghum tribe. Six *Saccharum* species are now recognized. Historically, sugar canes are derivatives of what is known as the *Saccharum* complex, which comprises the interbreeding genera of *Saccharum*, *Erianthus*, *Sclerostachya*, *Narenga*, and *Miscanthus*. The most primitive *Saccharum* species, *S. spontaneum* L., a highly variable and vigorous, but thin-stemmed, fibrous cane low in sugar, is believed to have originated in northern India. Subsequent modification, movement, and hybridization generated various Asian, Pacific, and African forms. Still being debated is the botanical lineage of *Saccharum officinarum* L., clones of which—so-called noble canes—furnished the raw material of plantation-based sugar industries from the latter part of the eighteenth century until the early 1900s. This species—thick-stemmed, soft-rinded, rich in sugar, and originally selected for chewing—is generally thought to have evolved in eastern Indonesia or New Guinea from the wild cane *Saccharum robustum* Brandes and Jeswiet ex Grassl. An alternative theory has *S. officinarum* derived from the Chinese sugar cane, *S. sinense* Roxb. emend. Jeswiet, which was carried to the Philippines, making that area the likely site of initial hybridization and development of *S. officinarum*. In any event, *S. officinarum* probably became a cultivated food plant about 5000 or 6000 years ago. In the course of time, sugar cane of one form or another spread eastward across the Pacific and north-westward to India, and thence via Persia and the Mediterranean basin to the Atlantic seaboard, finally reaching the New World in 1493 on the second voyage of Columbus.

The first cultivars grown in the Western Hemisphere were male-sterile, and the possibility of deliberately breeding new varieties was not generally recognized until the late 1800s after the fertility of cane seed was definitely established simultaneously in Barbados and Java. Finding that adaptability to less-than-optimal ecological conditions and, above all, resistance to diseases was unobtainable within the genetic variability of *S. officinarum*, breeders eventually began to cross noble canes with other *Saccharum* species and cross the progeny back with noble canes, a process called nobilization. Today, most cane-growing countries in the world pursue their own breeding programs. In addition to disease resistance and high yields in the local conditions over several seasons, the aim is to obtain varieties tailored to modern production methods such as suitability for mechanized harvesting and herbicide tolerance.

**Environment and cultivation.** Sugar cane is grown in about eighty countries between roughly 30° latitude north and 30° latitude south. Often described as a tropical crop, much cane is actually grown in subtropical areas. The ten leading producers are India, Brazil, China, Thailand, Australia, Mexico, Cuba, the United States, Pakistan, and South Africa. Sugar cane is a very adapt-

Early engraving by Theodore de Bry showing Caribbean Indians working as slaves in a Spanish sugar mill. COURTESY OF THE LIBRARY OF CONGRESS.

able plant that can be grown successfully on a wide range of soils. It grows best under ample sunlight in moist hot climates where a period of heavy rainfall is followed by a cool and dry season to increase sugar content and facilitate harvesting, or with controlled irrigation. Depending on location and other factors, the crop is ready for harvesting ten to twenty-four months after planting. In a harvesting period lasting between three and eleven months, again depending on location, the stems are cut, topped, and stripped of leaves by hand or machine. Yields vary widely from less than forty metric tons to more than one hundred metric tons of cane per hectare, equivalent, after processing, to upwards of four metric tons of sugar per hectare. Cut cane deteriorates rapidly and must be processed promptly to avoid heavy loss of sucrose. After the first harvest, underground buds on the stool throw out new shoots, and the plant develops a new root system. This allows the production of second, third, or more crops, known as ratoons, in a similar or shorter growth period and at less cost. The complete crop cycle usually lasts three to ten years, the field being replanted when the yield drops below an economic level.

**Structural and economic aspects.** As a perennial ratoon grass, sugar cane does not easily lend itself to crop rotation and is usually grown in monoculture. Extremely labor-intensive until mechanization, particularly at harvest time, sugar cane has been regarded as the archetypal plantation crop, produced in large enterprises employing many low-skilled workers under the supervision of a few skilled managers. Broadly speaking, this was true for the export-oriented sugar cane industries of the colonial period and lies at the heart of the historical association of sugar with slavery. However, the organizational structures of sugar cane agriculture have long exhibited great diversity, even in territories described as

plantation economies, and range globally from small-holders with less than two hectares to miller-planter complexes in which a centralized management controls thousands of hectares as well as a factory.

Throughout the world, cane farming operations from soil preparation to harvesting and transport are increasingly mechanized. A bulky crop of low unit value, sugar cane presents formidable materials-handling problems. Until the 1960s, Hawaii, Louisiana, and Queensland were the only cane-growing areas to have mechanized both cutting and loading. Despite the arduous nature of the work, growers have tended to retain manual harvesting using heavy machete-type knives as long as economically feasible because mechanized harvesting systems entail extensive field reforms and modifications of transport equipment and factory reception facilities and because of the increased extraneous matter content in mechanically harvested cane, at least in the early years. Rising labor costs and better machines, however, have led to the progressive mechanization of harvesting operations in one country after another. In some areas, mechanization proceeded in stages, starting with the piling and loading of hand-cut cane or wholestalk harvesters; other areas have gone straight to combines that cut, chop into billets, clean, and load in a continuous operation.

## Sugar Beet

**Physical characteristics.** The root of sugar beet, in which sucrose accumulates, consists, from the top down, of the epicotyl or crown, the hypocotyl or neck, and a swollen taproot. Roots vary greatly in size but average about 600 grams. The crown is the part above the lowest leaf scar; it is stem tissue with leaf buds and supports a rosette of leaves, the botanical engines that put the sucrose into the root. The hypocotyl, the region between crown and tap root and the thickest part of the root, extends from the lowest leaf scar to the uppermost lateral roots. Epicotyl and hypocotyl make up the part of the root that rises above ground. Depending on variety, plant population, and the various factors affecting growth, these two sections account for about 20 percent of the length and weight of the entire root. The white-fleshed tap root has two grooves on opposite sides from which lateral roots emerge. It tapers off to a tail less than one centimeter thick that with the hairlike ancillary roots often extends two meters or more deep into the soil.

The sucrose and nonsucrose constituents of sugar beet are not distributed uniformly in the root; sucrose content and purity are higher in the middle of the root than in the crown and tail. Hypocotyl and taproot together contain 14 to 20 percent sucrose. In harvesting, the beet is topped below the green leaf stalks of the epicotyl, a certain margin in the upper hypocotyl being allowed, while the tail usually breaks off in the lifting and subsequent handling of the root. A biennial, sugar beet flowers and bears seed in the second season, but is harvested for sugar in the first.

**Origin and geographical spread.** Sugar beet, *Beta vulgaris* L., is a member of the Chenopodiaceae or goose-foot family. Four distinct types of the species are cultivated: sugar beet, garden (red) beet, leaf beet and Swiss chard, and fodder beets. Sugar beet, the second major source of the world's sugar supply, is commercially by far the most important of the four types. Wild forms from which the crop could have been derived are widely distributed throughout the Mediterranean region and the Middle East. It is not known when the beet was taken into cultivation, but use of the plant medicinally and as a vegetable was already well established in Greek and Roman times. Cultivars with swollen roots, the result of human selection, are recorded in northern Europe from the sixteenth century onwards. The French agriculturist Olivier de Serres (1539–1619) compared the liquid from cooked red beet to sugar syrup. In 1747, Andreas Sigismund Marggraf (1709–1782), a member of the Berlin Academy of Sciences, reported having extracted from red and white beets a substance identical with cane sugar. Towards the end of the 1700s, another academician, Franz Carl Achard (1753–1821), began to grow white beets for sugar production, first near Berlin and then in Silesia where in 1802 he opened the first beet sugar factory. Achard's beets had a sugar content of up to 6 percent, but this was raised by simple mass selection to about 9 percent by the 1830s. Since then, thanks to advances in breeding methods, the sugar content in beets has roughly doubled. Average German beet yields per hectare have also more than doubled, so that a hectare of beets now produces approximately four times as much sugar as it did in the mid-1800s.

**Environment and cultivation.** Sugar beet is currently grown in nearly fifty countries, all save Chile in the northern hemisphere and most enjoying moderate summer temperatures and at least 250 millimeters of rainfall during the growing season except in areas where irrigation is available. Beet is successfully cultivated in many soils, but a deep loam, moist yet well-drained, is best. Member countries of the European Union, the United States, Turkey, Poland, Ukraine, Russia, and China are the leading producers. Sown in spring, the crop is lifted before the first frosts are expected. Different from cane, harvested beet can be stored for months under suitable conditions without intolerable loss.

**Structural and economic aspects.** Unlike cane, beet is grown in rotation with other crops and is closely integrated in the farming systems practiced in the regions where it is cultivated. As a root crop, it improves soil conditions. The beet tops can be used for fodder or, when plowed in, provide organic manure. The beet pulp remaining after sugar extraction is also used for animal feed, in contrast to bagasse, the fibrous residue of cane processing, which mainly ends up as factory boiler fuel. Like cane, beet was formerly an extremely labor-intensive crop. In the case of beet, however, not harvesting but thinning out the seedlings after emergence to create space

between plants was the operation most resistant to the reduction of labor requirements. Until the advent of monogerm varieties with single flowers at each inflorescence node, sugar beet bore clusters of flowers which gave rise to multigerm seed balls. Even where animal- or tractor-drawn implements replaced the hand hoe in blocking out excess seedling clusters, the final singling to one plant per clump had to be done manually. Labor shortages in the United States during World War II spurred the introduction of mechanically segmented seed (followed after the war by decorticated seed) with a large proportion of single germs, better suited for precision drilling but at the risk of poorer germination and an uneconomic plant population in the field. The same drawbacks adhered to the seed of early genetically monogerm varieties, and the total elimination of manual labor in sugar beet agriculture did not become possible until the arrival of improved forms since the late 1960s.

### Other Natural Sweetener Sources

**Polysaccharide-bearing plants.** In 1811, a Russian-German chemist, K. S. Kirchhof, working in St. Petersburg, discovered that adding diluted sulfuric acid to cooked potato starch produced a sweet syrup containing glucose. A year later, the first starch sugar factory was established in Germany. While the technological details would vary depending on the source of starch—cereals, roots and tubers, or stem pith, the door was opened to obtaining sweeteners from a wide range of plants. Syrup from corn (maize), rather than potatoes, has been made in the United States since the mid-1800s. Elsewhere, the raw materials could be sweet potatoes, tapioca (cassava, manioc), rice, wheat, and sago. But while such starch-based syrups could compete to some extent with cane and beet sugar in processed foods and drinks, their application was constrained by the fact that glucose is markedly less sweet than sucrose. This disadvantage was overcome in the second half of the 1960s and early 1970s by a new process of continuous enzymatic isomerization of glucose to fructose. (In essence, a glucose solution is passed through columns or beds containing immobilized enzyme, which changes the atomic arrangement of glucose into that of fructose.) The result is high-fructose corn syrup (HFCS), called isoglucose in Europe. Unlike the older glucose syrups, an equilibrium fructose-glucose syrup compares in sweetness and in other respects to invert sugar syrup made from sucrose. This greatly widened the possibilities of using starch sweeteners in industries such as the soft-drink industry, that were major users of sucrose. In the second half of the 1970s, further technological advances brought onto the market second-generation syrups with higher fructose contents, which deliver more sweetness with fewer calories, thanks to the fact that fructose is sweeter than sucrose. Since 1985, consumption of HFCS, glucose syrup, and dextrose, on a comparable dry basis, has exceeded that of beet and cane sugar in the United States, but this is so far the only country in which sucrose is no longer the leading sweetener.

Certain plants lay down fructose polymers as energy reserves in place of or in addition to starch. Inulin—found in, among other plants, chicory and Jerusalem artichoke—belongs to this category of polysaccharides. Inulin syrup is produced on an industrial scale in the European Union and falls under the EU's sugar and sweetener market regime.

**Palms.** Various species of palms have for centuries been tapped—notably in southern and southeastern Asia—for their sweet sap, which is drunk fresh or fermented. Alternatively, the sap has been boiled down until it sets to a solid mass of fudgelike consistency, called gur or jaggery, or is distilled to produce arrack. Among palm species exploited in these ways are the palmyra (*Borassus flabellifer*), the toddy fishtail or jaggery palm (*Caryota urens*), the coconut palm (*Cocos nucifera*), the nipa palm (*Nipa fruticans*), and a wild date palm (*Phoenix sylvestris*) related to the palm of commercial date production (*P. dactylifera*), the fruits of which are also a source of sugar.

**Maples.** Several species of the maple family, as well as birch and elm, can be tapped to make syrup and sugar, but the main source is the sugar maple, *Acer saccharum*. Maple syrup has been made in North America since before the arrival of the first European settlers. It was an important sweetener in the northern United States and Canada until overtaken by beet and cane sugar. A peculiarity of the maple sap run is that it takes place when the tree is still dormant. The sap that will make syrup differs from that circulating in the growing tree. Its flow is triggered by a thaw following a hard frost. The mechanics of the run are believed to involve changes in osmotic, water and gas pressures caused by the translocation of sugar stored in trunk xylem tissue the previous summer as the trunk warms up on a sunny late-winter day. Fresh sap contains up to 3 percent sucrose. Evaporation by boiling in open pans, which also adds color and the characteristic maple syrup flavor, raises the sucrose content to around 62 percent and reduces the water to 35 percent in the final product. At higher concentrations, the sugar crystallizes when the syrup cools. Thirty to 40 liters of sap make one liter of syrup.

Production methods have improved over the years. The Indian technique of cutting a wide gash in the trunk was hard on the tree. The colonists introduced the practice of making a small hole with an auger—now done with power drills—and fitting a spout from which a bucket was suspended. In recent times, plastic tubing has been adapted to collect the sap from an entire stand of trees, and central evaporator plants, with instruments to monitor boiling temperature and syrup concentration, now serve whole producer communities.

**Sorghum.** A near relative of sugar cane, sweet sorghum or sorgo (*Sorghum vulgare*), a native of Africa, was, for a while in the second half of the eighteenth century, thought to have the potential for becoming a mainstream source of sugar in the United States. Although it could

not compete against the growing availability of beet and cane sugar from about 1880 onwards, sorghum syrup is still produced on a small scale.

**Mabua or Mowrab Tree.** Several trees of the genus *Madhuca* or *Bassia* (Sapotaceae) bear sweet fleshy edible flowers. Those of *M. indica*, also named *M.* or *B. latifolia*, were mentioned in Indian medical writings as a source of sugar as early as the third to seventh centuries A.D.

**Manna.** The word “manna” has various meanings. The biblical manna may have been wind-borne edible lichens, *Lecanora* (*Sphaerothallia*) *esculenta* or other species of the same genus. Two Middle Eastern shrubs, *Alhagi maurorum* and *A. pseudalhagi*, exude a sweet resin that hardens and can be collected by shaking the bushes over a cloth spread on the ground. Insect punctures in the stem of the French tamarisk, *Tamarix gallica*, of the same region produce drops of a honeylike exudation called manna. The word is also used for the incrustations formed by the sap that flows when incisions are made in the bark of the Sicilian flowering ash, *Fraxinus ornus* L. (Oleaceae). Numerous other sources of resinous mannas are listed in herbalist and pharmacological literature. Although not in all cases, the principal chemical constituent of such mannas is mannitol, also called mannite, a colourless sweet-tasting crystalline alcohol.

**Stevia.** The leaves of *Stevia rebaudiana* Bertoni, a wild shrub of the Compositae family that is native to Paraguay, contain a complex mixture of sweet diterpene glycosides. Stevioside, a high-intensity sweetener 250 to 300 times sweeter than sucrose, is extracted from the leaves and used as a sweetener in South America and Asia. Because of unresolved toxicological concerns, Stevia and stevioside cannot be sold as food or food ingredients in the European Union.

**Protein sweetener sources.** A number of plants yield taste-modifying proteins that function as natural sweeteners of very high intensity (thousands of times sweeter than sucrose). Some are believed to have been used for centuries by indigenous peoples to improve flavor and suppress bitterness in food and drink. The most widely known, thaumatin, is contained in the aril of the seed of *Thaumatococcus daniellii* Benth. (Marantaceae), a West African shrub. Monellin from the berries of the West African *Dioscoreophyllum cumminsii* Diels (Menispermaceae) is another example.

**SUSTAINABLE AGRICULTURE.** From a technological and economic standpoint, agriculture today represents one of the success stories of the modern era. Despite an ever increasing global population, and a corresponding gradual decrease in the availability of nonrenewable natural resources such as energy, land, and water, farmers throughout the world have responded to the challenge by increasing total and per area production levels every year. This agricultural miracle is due to a long tradition of farmer self-reliance, ingenuity, and perseverance, and to the support provided to farmers by many private and public institutions. Especially noteworthy is the support provided by a network of agricultural research universities in North America and Europe. Furthermore, crop productivity has improved in the developed world, and in many Third World countries as well. By the 1970s, many Third World countries in Asia and Latin America had actually reached self-sufficiency with respect to several primary staple grains.

The race toward increased crop yields began in the mid- to late 1800s in precapitalist England. Ever since then, scientists, environmentalists, and economists have issued words of caution concerning environmental and social issues arising from modern agriculture. By the mid- to late twentieth century, some of the more negative en-

### SOME KEY UNDESIRABLE SIDE EFFECTS OF MODERN AGRICULTURE

- Unsustainable irrigation programs throughout the world are resulting in an undesirable buildup of salinity and toxic mineral levels in one out of five hectares under irrigation. Thus, agricultural water, a nonrenewable resource whose use has tripled globally since 1950, has to be used more efficiently to minimize salinization problems.
- Excessive soil erosion, in the range of fifteen to forty tons per hectare annually, results in the loss of productive farmland in many parts of the world. Forested areas, a refuge for wildlife and biodiversity (biological diversity), are then often turned into agricultural fields to compensate for the loss of the abandoned eroded areas.
- The indiscriminate use of pesticides is affecting human health and wildlife populations, as first reported to the population at large in Rachel Carson's book *Silent Spring* (1962).
- The increased concentration of farms into larger and larger farm holdings is reducing the number of small family farms, believed by many to represent the heart of rural communities and to be key stewards of the environment.
- The trend toward larger farms and plantation-type monocultures is leading to a loss of global biodiversity. Biodiversity, many argue, may be a critical ecological feature that allows the continued survival of humans on earth.
- The excessive reliance on synthetic fertilizers, and the improper use and disposal of animal wastes is leading to the breakup of natural nutrient cycles. This causes an undesirable buildup of nutrients and salts in aquifers, affecting wildlife in aquatic habitats.

environmental and economic side effects of modern capital-intensive agriculture became evident in many parts of the world. The increased realization that modern agriculture had serious side effects, resulting in reduced environmental quality, health concerns, and economic insecurity for the traditional family farm, led in part to what is known today as a global "Sustainable Agriculture" movement.

#### Definition

Because agricultural systems are so diverse, based on farm size, location, crop being grown, socioeconomic background, among many other factors, and because the

movement has become so widespread globally, sustainable agriculture has come to represent different things to different people. Nevertheless there are some common threads, concepts, and beliefs. In the most general terms, sustainable agriculture describes systems in which the farmer reaches the goal of producing adequate yields and good profits following production practices that minimize any negative short- and long-term side effects on the environment and the well-being of the community. The major goals of this approach are thus to develop economically viable agroecosystems and to enhance the quality of the environment, so that farmlands will remain productive indefinitely.

### Why Sustainable Agriculture? History and Future Prospects

Ancient history, ranging from the Egyptians to the Romans to the Mayans, indicates that poorly managed agriculture can lead to the eminent decline of entire civilizations. By the midpart of the twentieth century, symptoms began to appear, documented by scientists, that some aspects of modern agriculture were unsustainable, leading in many cases to a decline in environmental quality and human quality of life. The undesirable side effects of modern agriculture, some believed, were threatening

### WHAT IS SUSTAINABLE AGRICULTURE? SOME KEY DEFINITIONS

*Sustainable agriculture* involves farming systems that are environmentally sound, profitable, productive, and compatible with socioeconomic conditions (J. Pesek, in Hatfield and Karlen, *Sustainable Agriculture Systems*).

*Agroecology* is a field of research used to implement sustainable systems. It is the application of ecological concepts and principles to the study, design, and management of sustainable systems.

A *systems* approach is used to study and research sustainable systems. The goal is to study the farm as an entity made up of all its components and their interrelationships, together with relationships between the farm and its environment.

*Key components* of sustainable systems include enhanced internal nutrient cycling on the farm; improved soil quality through additions of organic matter and reduced soil erosion; increased vegetational diversity to promote natural systems of pest control; and alternative marketing programs that increase profits and minimize overhead costs.

## BASIC FEATURES AND CONCEPTS OF SUSTAINABLE SYSTEMS

1. The need to maintain or improve soil quality and fertility. This is often attained by increasing the organic matter content of the soil, and by minimizing losses from soil erosion.
2. Production programs are designed to improve the efficiency of resource utilization. This will result in the most cost-effective use of water, fertilizers, and pesticides.
3. An attempt is made to improve internal nutrient cycles on the farm, which will reduce the dependence on external fertilizers.
4. Efforts are made to improve biological diversity on the farm. This will result in improved natural suppression of pests, and may also help to improve internal nutrient cycling within the farm.
5. Farm management and marketing programs are designed to minimize overhead costs and to increase returns, often by following alternative marketing schemes.

the lands and the very livelihood that farmers were trying to sustain. In contrast, from a historical perspective, scientists knew that civilizations that did follow sustainable practices were indeed able to thrive for centuries. Thus, by incorporating the use of production techniques developed by the latest agricultural research, along with some of the farming practices that proved effective through centuries of farming in many areas, a set of recommended management practices was established in individual production regions.

The future goal of farming communities is to strive to use current sustainable practices and to utilize the latest production techniques to remain competitive in the global agricultural market. For this to take place, a close communication link has to be maintained between rural communities, researchers, and society at large. This link gives urban communities a better understanding of issues affecting farmers, including the farmers' role as stewards of the environment, and of the economic realities of providing the public with a consistently healthy and safe food supply.

### Implementing Sustainable Systems

An important aspect of sustainable agriculture is that it does not represent a specific set of agricultural practices that farmers need to follow step by step, like one would a recipe, to reach a specific goal. Instead, the concept rep-

resents more of a paradigm shift that encourages farmers to seek their own path, one that best fits the farm's particular conditions, and leads toward a more environmentally friendly approach without sacrificing yields or profits. Similarly, sustainable agriculture is not a specific target, but instead is more of a process that every farmer pursues as part of the daily farm operations. Thus, because agricultural systems are so diverse, farmers may choose among a myriad number of agricultural practices and techniques available to produce crops more effectively.

**SWEETENERS.** *See* **Sugar and Sweeteners.**

**SWEET POTATO.** Sweet potato (*Ipomoea batatas*) is in the botanical family Convolvulaceae along with common plants, such as bindweed and morning glory. The generic name *Ipomoea* comes from the Greek words "*ips*," meaning bindweed, and "*homoios*," meaning similar. Sweet potatoes should not be confused with ordinary potatoes (*Solanum tuberosum*) as they are entirely unrelated, although their uses can be similar. Orange-fleshed sweet potatoes are often known as yams, especially in the southern United States, but they are quite different from true yams (*Dioscorea* sp.) in growth habit and use. Furthermore, unlike true yams, the greens of sweet potatoes are edible and provide an important source of food in Africa and Asia.

## Identification

Sweet potato is a perennial that is usually grown as an annual. It grows from underground tuberous roots with trailing, twisting stems that can be as long as twenty feet (six meters). Leaves are variable in shape, size, and color but are generally more or less heart-shaped and green with purple markings. The single flowers are funnel-shaped and white or pale purple but are rarely seen in temperate regions. Roots grow where stem nodes touch the ground, and most develop into the edible storage roots, usually four to ten storage roots per plant.

## Diversity

The International Potato Center (CIP) in Peru holds the largest sweet potato gene bank in the world with more than 6,500 wild, traditional, and improved varieties. Many of these are unique to a particular country or region. For example, an anthropologist in Irian Jaya found forty different cultivars of sweet potato growing in just one community garden. In contrast, Stephen Facciola's *Cornucopia II* (1998) lists only twenty-five different varieties available for the whole United States. Sweet potato flesh can be white, yellow, purple, red, pink, violet, and orange, while skin color varies among yellow, red, orange, and brown. Varieties with pale yellow or white flesh are less sweet and moist than those with red, pink, or orange flesh. They also have little or no beta-carotene and higher levels of dry matter, which means their textures are drier and more mealy and they stay firmer when cooked. Sweet potatoes also vary enormously in size, shape, taste, and texture, although all are smooth-skinned with roots always tapered at both ends.

## Nutrients

All varieties of sweet potato are good sources of vitamins C and E as well as dietary fiber, potassium, and iron, and they are low in fat and cholesterol (see the Table for more detail). The orange- and red-fleshed forms of sweet potato are particularly high in beta-carotene, the vitamin A precursor.

## Origins

Scientists debate the exact place of origin of *I. batatas*, although the evidence points toward Central America rather than South America. They are no longer found growing in the wild, but it is possible that the wild Mexican sweet potato *I. trifida* is an ancestor. Sweet potatoes have been cultivated for more than five thousand years, and fossilized remains found in the Andes have been dated at about 8,000 years old. Genetic studies suggest the likelihood that in early times sweet potatoes were carried by the local people from island to island, spreading gradually across the Pacific from Central and South America to eastern Indonesia, New Guinea, Polynesia, and New Zealand. Christopher Columbus is credited with taking sweet potatoes from the New World back to Spain, from where they spread through the warmer regions of Europe and were transported to other parts of

Asia and to Africa by Spanish and Portuguese explorers and traders. Sweet potatoes were grown in gardens by North American Indians and were an important staple food during the American Revolutionary War and the American Civil War. They were also an essential part of the diet of the slave population in southern states. Most large plantations had a sweet potato plot and root cellars beneath cabins for potato storage.

## Popularity

At the beginning of the twentieth century sweet potatoes were the second most important root crop in the United States. In 1920 the per capita consumption of sweet potatoes was thirty-one pounds (fourteen kilograms), but consumption steadily declined. In 1999 consumption was only 4 pounds (1.8 kilograms) per person (U.S. Department of Agriculture, 2000).

A sweet potato plant depicted in Johann Sigismund Elsholtz's *Diaeticon* (1682), one of the first works to discuss the health and medical value of this New World vegetable. ROUGHWOOD COLLECTION.

Sweet potatoes grow in all warm, humid areas of the world and at the beginning of the twenty-first century were the seventh largest world food crop, 95 percent of which is produced in developing countries. They are typically grown by small farmers, often on marginal ground. This crop plant has a long history of saving lives. It matures fast, is rich in nutrients, and is often the first crop planted after a natural disaster, providing abundant food for otherwise starving populations. In eastern Africa the sweet potato is known as “the protector of children” or *cilera abana* because it is often the only food that stands between a child’s survival and starvation.

### Growing Sweet Potatoes

Sweet potatoes are tropical plants that can also be grown in the summer in temperate regions as long as they have at least five frost-free months combined with fairly warm days and nights. They can be grown from vine cuttings or by planting pieces of the roots. To grow new plants, place one or more sweet potatoes in a bed of sand and cover with a couple of inches of moist, sandy soil. When the sprouts reach about 10 inches (25.4 centimeters), detach by twisting and transplant to the place they are to grow. Push sprouts about 3 inches (7.6 centimeters) into the ground and water well. Leave a distance of about 1 foot (30 centimeters) between plants and 3 feet, 3 inches (1 meter) between rows. Sweet potatoes do best in full sun with fertile, open sandy-loam soils. They also like some added manure (well rotted) and compost, although they should not be given too much nitrogen as this encourages leaf growth at the expense of root growth. They benefit from regular additions of potash. Roots will be bigger and easier to harvest if sprouts are planted into

raised mounds about 1 foot (30 centimeters) high. This is particularly important in heavy or wet soil. Once established, apart from occasional weeding, sweet potatoes need little care.

### Harvesting

Roots are harvested as the leaves begin to yellow in the fall. They are then brushed clean and left to cure. Traditionally curing involved stacking the potatoes in the field or garden, covering them with sand, and leaving them for several weeks. Sweet potatoes in commercial production are cured in rooms with humidity between 75 percent and 80 percent and temperatures between 80°F and 86°F (27°C and 30°C). Curing heals cuts and reduces decay and shrinkage during storage, and it converts some starches to sugars, improving the flavor. Once cured, sweet potatoes can be stored for several months, and white-fleshed varieties last as long as ten months.

In the United States most of the sweet potato crop is canned. These are usually the smaller roots. Roots of good size are sold fresh, and any that are too large are generally processed into baby food.

### Buying

When buying sweet potatoes, always choose ones that are firm with even skin coloration and no signs of decay. They should never be stored in the refrigerator. Keep them in a cool, dry, well-ventilated container (a basket is ideal) at about 55°F to 60°F (13°C–16°C). Generally they should be used within two to three weeks of purchase because it is not possible to determine how long they have already been stored before purchase.

### Who Grows Sweet Potatoes?

According to figures released by CIP, more than 148.77 million short tons (135 million metric tons) of sweet potatoes are grown worldwide. China is by far the largest producer with about 87 percent of the crop, nearly half of which is fed to animals. The rest of Asia accounts for 6 percent, Africa 5 percent, Latin America 1.5 percent, and the United States 0.45 percent. In most developing countries, where the sweet potato is part of the staple diet, the white- or cream-fleshed forms with a bland taste are usually grown. These potatoes have a high dry matter content, which means they are a good energy source, which is vital for a staple food. In developed countries, where the sweet potato is used more as a vegetable or for sweet dishes, the red- or orange-fleshed types are preferred for their moist flesh and sweet flavor. The U.S. sweet potato crop was worth \$214,980,000 in 1999, and just under a third of the crop was grown in North Carolina. Louisiana, Mississippi, and California also grow significant quantities. The largest European producer is Portugal with only .02 percent of world production. These figures clearly illustrate that sweet potatoes are an important crop in third world countries but are a secondary food-stuff in first world countries.

## Preparing and Eating

Sweet potato roots can be boiled, steamed, baked, and fried. They are also canned or dried and made into flour, cereal, and noodles. Like pumpkins, sweet potato roots are often used in sweet dishes, such as pies, puddings, biscuits, cakes, and desserts. In some countries roots are processed to produce starch and fermented to make alcohol. Cooked red- or orange-fleshed sweet potato roots are sweet, soft, and starchy with a flavor that resembles roasted chestnuts and baked squash. Sweet potatoes are prepared by scrubbing and cutting into appropriately sized pieces. Leave the skin on if they are to be baked, boiled, or steamed; peel before frying. Cooking in the skin preserves more of the nutrients. Once the roots are cooked (when a knife can be easily inserted), they can be served whole or peeled and mashed, pureed, or sieved and served as a sweet or savory vegetable, depending on what is added.

In the United States sweet potatoes are probably best known for their use in pies and as a candied vegetable. They are a traditional accompaniment to Thanksgiving dinner and often appear on the menu at other festival times, such as Christmas and Easter. Sweet potatoes can be substituted for potatoes, apples, or squash in almost any recipe. Cooked, mashed sweet potatoes are also used to replace some of the wheat flour in breads, cakes, muffins, and cookie recipes, as is sweet potato flour. Sweet potatoes cooked in their skins can be frozen. Wrap each piece in aluminum foil or freezer wrap, place into a freezer bag, and freeze.

In third world countries sweet potatoes are processed into starch, noodles, candy, desserts, and flour. This allows the farm household to extend the availability of the crop. In China, for example, sweet potato starch production has become an important cottage industry, while in Uganda sweet potatoes are sliced and dried, which allows them to be kept for about five months. The dried pieces are also ground into flour, which is then rehydrated and eaten as a thick porridge known as *atapa*.

Although usually the roots are eaten, young leaves and the tips of vines can be harvested, washed, and boiled as a green vegetable or added to stir-fries. All parts of the sweet potato are used as stock feed, although the roots are often cooked first.

## As a Medicine

Sweet potato roots and leaves are used in folk remedies to treat illnesses as diverse as asthma, night blindness, and diarrhea. Easily digestible, they are good for the eliminative system. It is believed they bind heavy metals, so they have been used to detoxify the system.

## Sweet Potatoes in Africa

In eastern and southern Africa some 3 million children under the age of five suffer from xerophthalmia or dry eye, which causes blindness. Dry eye is caused by a lack of vitamin A in the diet, and many of the affected chil-

dren die within a few months of becoming blind. The yellow- and orange-fleshed varieties of sweet potatoes are high in beta-carotene, which can be converted into vitamin A in the intestines and liver. It has been shown that even small amounts of these sweet potatoes as a regular part of the diet will eliminate vitamin A deficiency in adults and children. African countries have traditionally grown white-fleshed sweet potatoes, which are low in vitamin A. A ten-year research project concluded that varieties high in beta-carotene could compete with production levels of the white-fleshed varieties and would be acceptable to local tastes. Consequently CIP and related organizations launched a regional effort to encourage African women to also grow orange-fleshed varieties.

At the same time researchers at CIP have combined parental clones of sweet potatoes to yield a group of yellow and orange potatoes with high dry matter (a characteristic of the white-fleshed forms of sweet potato) that they believe will be more acceptable to African consumers. In Kenya sweet potatoes are mostly grown in the densely populated Western Province, where often more than half the crop is destroyed by a virus. In 2000 the Kenyan Agricultural Research Institute released genetically modified sweet potatoes with increased disease resistance and assured the public that these potatoes would be largely resistant to the virus.

## Twenty-first Century Changes

In the last four decades of the twentieth century the uses of sweet potatoes diversified beyond their classification as subsistence, food security, and famine-relief crops. In particular the last decade of the century saw a concentrated, coordinated effort to fully realize the potential of this crop. The hoped for result is that millions of subsistence landholders in Africa, Asia, and Latin America will be able to use sweet potatoes for food, stock food, and processed products and to generate income.

The United States is also exploring the potential of sweet potato products. A patent was granted for the production of bread made from 100 percent sweet potato flour. It is hoped that these products will appeal to consumers who are allergic to grain breads and flours. Also scientists at two different institutes in the United States have developed genetically modified sweet potatoes containing edible vaccines. One of these vaccines works against hepatitis B and the other against the Norwalk virus found in food that has not been handled or stored correctly. Edible vaccines such as these may provide cheap protection for some of the poorest people in the world.

**SWEETS.** See *Candy and Confections*.

**SWIDDEN.** Swidden is an agricultural strategy that necessitates the slashing, cutting, felling, and burning of forested areas for the planting of impermanent garden plots or agricultural fields, and that has been the mainstay of horticulturalists and peasant farmers in the tropics and primeval forests of the world for the better part of the past four to eight thousand years. This method of agricultural intensification, more widely known as "slash-and-burn" agriculture, is called *tlacolol* or *milpa* agriculture in Mesoamerica. It is often associated with patterns of shifting cultivation or extensive agriculture via which soil exhaustion or weed intrusion necessitates plot rotation and fallow cycles.

Tropical soils are extremely fragile, and agriculture in the tropics tends to deplete soil-based nutrients rapidly, resulting in decreasing yields from such parcels after just a few seasons. In order to stimulate the regeneration of soil nutrients through the growth and decay of tropical vegetation, swidden agriculturalists typically abandon or fallow such plots for as many as twenty-five years. These cycles of slash-and-burn field preparation, cultivation, and fallow, and the necessity of shifting or relocating cultivation to adjacent or new fields on a cyclical basis, play a key role in the social, economic, and political configurations of those societies that resort to such strategies of agricultural intensification in tropical or otherwise forested environments.

### Swidden and Shifting Cultivation

According to cultural ecologist Robert Netting, a broad spectrum of agricultural systems exists within traditional or otherwise "technologically simpler" societies in what

today constitute some of the nations of the Third World. Such systems range from those that require a constant shifting from field to field within virgin forests to intensive agriculture supported by irrigation works in year-round production. Within this spectrum can be identified a variety of swidden system strategies that include short-term as opposed to long-term fallowing, sectorial fallowing, forest-fallow, bush-fallow, and short-fallow cultivation (pp. 65–66). The latter three types, originally identified by agricultural economist Esther Boserup, are defined on the basis of land-use types and the total period of cultivation as opposed to periods of fallow. Whereas forest fallow may see the cultivation of a single swidden parcel for a period of one to two crop years, that same field may then lie dormant (fallow) for a period of twenty to twenty-five years. On the other hand, bush fallow may encompass a period of one to eight successive years of cultivation, and only six to ten years of fallow. Finally, the short-fallow system may range from a very short or variable period of months or seasons of cultivation to a one-to-two-year fallow cycle. In each of these systems, the extent to which productive yield is maintained or enhanced by the regeneration of tropical vegetation and its subsequent slashing and burning is key to the nature of the system employed. Similarly, in those areas where population growth and settlement place constraints on the availability of viable forest parcels, agricultural intensification may necessitate an increase in the number of parcels devoted to short-fallow cropping.

### Origins and Development

Archaeologist Richard E. W. Adams has noted broad similarities in the nature of settlement patterns and artifact distributions between the ancient Maya swidden farmers of Mesoamerica and early Danubian swidden agriculturalists of Europe. According to Adams, the expansion of Danubian farmers into western Europe at 5000 B.C.E. resulted in the rapid and extensive spread of Danubian settlements and traditional arts and technologies across a vast area. Adams attributes this pattern to the use of slash-and-burn (swidden) agricultural systems in the primeval forests of Europe. Such a pattern resulted in the rapid establishment, abandonment, and reoccupation of villages over vast areas in a pattern reminiscent of that identified with swidden agriculturalists the world over (p. 119). According to Robert Gary Minnich, similar demographic and cultural patterns have been identified with swidden practices introduced by the Slavs to the eastern Alps and northern Balkans in the sixth century (pp. 96–98). Such practices, in fact, persisted well into the twentieth century in the hilly and forested regions of Slovenia (p. 221).

Similarly, Myrdene Anderson has documented the introduction of swidden agricultural strategies into Norwegian Lapland from Finland at the beginning of the eighteenth century. In fact, a further review of swidden-related documents in the eHRAF Collection of Ethnographic

raphy (the online version of the Human Relations Area Files) will readily produce references to some forty-eight societies the world over whose cultural histories center on swidden agriculture or similar forms of agricultural intensification. Those societies range across the length and breadth of Africa, Asia, Europe, Middle America and the Caribbean, North America, Oceania, and South America.

### Traditional Crops and Agriculturalists

Swidden agriculture is practiced by diverse societies across a broad range of habitats, with the result that the methods, settlement patterns, cropping cycles, and traditional crops also vary widely. For instance, Bernard Sellato reports that the Dayak peoples of Borneo practice a range of agricultural pursuits, swidden being but one of many adaptive strategies. Among those Dayak groups that engage in swidden agricultural practices, crops consist of a variety of plant foods that are multicropped (planted within the same fields). According to Sellato, while the customary Dayak practice centers on the swidden cultivation of hill or dry rice in rain-forest clearings, such fields are seldom used to cultivate any more than a single crop of rice per year. However, while two crops of rice may be harvested on some occasions, cassava or manioc is sometimes cultivated within the same fields after the rice harvests. Once harvested, such fields are left to fallow for ten to twenty years. Sellato has also observed that the declining productivity of those swidden gardens closest to the communal dwelling place or longhouse often necessitates the relocation of village settlements and, thereby, accounts in large part for the shifting or semi-sedentary nature of the Dayak communities of Borneo, as is typical of other swidden farming communities the world over (p. 13).

In addition to hill or dry rice plantings in swidden parcels, Dayak communities also cultivate cassava, taro, yams or sweet potatoes, maize, sugarcane, beans, cucumbers and leaf greens, and various semiwild fruits. Despite a reliance on swidden crops, Dayak farmers nevertheless supplement their diets with fishing, hunting, and a pattern of animal husbandry centered on the consumption of dogs and cats, as well as chickens, pigs, and some ducks. While traditional Dayak swidden agriculture is largely reliant on the aforementioned crops, other cash crops include pepper, cloves, coffee, cocoa, coconut and oil palms, and rubber. In other contexts, permanent year-round garden plots and irrigation agriculture have displaced swidden practices in those contexts where population growth has resulted in the abandonment of traditional swidden patterns.

### Swidden Ecology and Its Consequences

Cultural ecologist Roy Ellen provides a detailed analysis of the cultural and ecological benefits and constraints posed by swidden agriculture. According to Ellen, declining crop yields identified with swidden farming are largely the result of pest infestations, plant disease, weeds,

the deterioration of soil nutrient content and composition, topsoil erosion, and changes in the number and composition of soil organisms or root biomass in any given parcel (p. 36). Because tropical soils are typically low in organic matter, slash-and-burn agriculture enriches soils to a limited extent and for a limited period of time by adding phosphorous, nitrogen, and potassium from the burned vegetation.

On the other hand, H. J. Albers and M. J. Goldbach found a correlation between the duration of cropping periods in swidden systems and the onset of species competition, resulting in an irreversible ecosystem transformation away from forest cover to grassland ecological regimes (pp. 262–263). In such instances, deforestation was the inevitable result of poor choices made by swidden farmers who were not concerned with the long-term benefits of longer fallow cycles.

In sum, despite the inherent challenges of farming in the tropics or primeval forests of the world, swidden remains a relatively efficient, and ecologically sound, system of agricultural production and resource management for the peoples of the Third World. This is particularly so when compared to those labor- and resource-intensive permanent and irrigation-based systems that dominate the nation-states of the First World. While the latter systems are ultimately more productive in terms of total crop yields, such productivity comes at great cost. The massive investment in agricultural equipment, fertilizers, pesticides, and personnel necessary to sustain intensive farming systems often outweighs the viability of such agricultural systems for the majority of those farmers whose only access to potentially viable agricultural land is largely restricted to the tropical and primeval forests of the Third World.

**SYMBOL, FOOD AS.** A symbol is an object, image, or action that is conventionally understood to represent something else. Food is particularly powerful as a symbol because it is so deeply embedded in everyday as well as celebratory life, and can therefore be read in many ways. Because it fulfills physical as well as emotional and psychological needs, it may be intentionally utilized as a symbol in some instances but not in others. And because food engages all the senses, it tends to evoke strong sensory and emotive as well as cognitive associations. This range of association adds to the potential symbolic power of food.

Three properties of symbols as defined by anthropologist Victor Turner are clearly demonstrated in food. The first is condensation: many ideas or actions are represented in a single formation. For example, turkey represents the American holiday of Thanksgiving, standing for the family gatherings, feasts, specific menus, and football games that commonly occur with the celebration. A second property is unification: symbols link disparate references. The turkey as symbol evokes abundance of natural resources, a romanticized New England heritage, patriotism, family harmony, and the fall season. The final property of symbols is polarization of meaning: they contain both ideological meanings (representing values, ethos, social norms) and sensory meanings (related to the objective properties of the symbol and representing physical aspects of life), merging these two poles and grounding conceptual references in felt experience. For example, apple pie is an American symbol of both patriotism and maternal nurturing, strengthening the referential power of each yet also lending the emotional associations of each to the other.

Foods become symbolic either through the presence of analogous qualities or by association in fact or thought with a particular reference. Analogous, or like, qualities include the physical structure or appearance of the item,

its texture, color, flavor, and even its nutritional components. For example, bananas are commonly used to represent a phallus; apples used to represent wholesomeness and innocence, as in "apple-cheeked children"; peaches to represent female attributes; caffeinated drinks to represent energetic and fun-filled personalities or activities.

Symbolic references for foods are also developed by association in fact or thought. Cherry blossoms bloom in early spring and are therefore used as a symbol to celebrate the change in season. Similarly, other crops ripen in the fall and become associated with that season. In the United States, pumpkins, corn, and apples are used to celebrate both autumn and the harvest-based holidays falling within that season.

Symbolic foods that develop their meanings through use and practice over time are "organic" symbols; they emerge from everyday usage, and their meanings are seemingly logical and inevitable within that cultural context. Symbols can also be created and imposed upon a culture. For these "invented symbols," individuals or institutions intentionally attach particular meanings to a food and attempt to control the interpretation given to that food.

As communicative tools, symbols can be manipulated for a multitude of purposes, on a personal as well as a cultural level. Food symbols are commonly exploited in marketing and advertising. Restaurant chains frequently attempt to associate themselves with a particular food item, for example, Red Lobster and Long John Silver with seafood, Wendy's with chili and square hamburgers, MacDonald's or Burger King with hamburgers and french fries. Similarly, advertising symbols can become attached to particular foods: the Jolly Green Giant with vegetables, Aunt Jemima with pancakes, the dignified Quaker with oatmeal.

Food's symbolic potential is also utilized for national, ethnic, and regional identity and pride. Americans rally around hot dogs, Spaniards around ham, Koreans around kimchi. Conversely, specific foods may be held up as distinguishing one group from another and as demonstrating that group's lesser worth.

Food symbolism occurs in all the activities surrounding the procurement, preservation, preparation, presentation, and performance of food as well as the food product itself. "Foodways" refers to this network of activities.

Procurement refers to the processes of obtaining food. Hunting, for example, can function as a symbol of manhood, of family tradition, of regional heritage. Purchasing groceries from specialty shops or catalogs rather than a local supermarket can signify economic status. Similarly, procurement can affect the referential meanings of a food item. Even though the food items are structurally identical, a bagel bought from the local corner deli can carry completely different emotional associations from one bought from the frozen bread aisle of a chain supermarket.

Preservation includes the means by which food is stored and kept for later use, the material forms used, the types of foods selected for specific types of preservation, and the physical arrangement of preserved goods. Smoke-houses used for curing hams can reference a southern U.S. heritage; similar structures for smoking fish represent a Midwestern background.

The size and design of refrigerators can symbolize social status (custom-designed to fit kitchen decor represents up-scale wealth), ethnicity (Americans tend to use large refrigerators and frequently possess an additional freezer to allow for the weekly or monthly shopping habits in the United States), or even occupation (university students use half-size ones to fit their smaller dorm rooms).

Preparation refers to the actual processes of turning the raw ingredients into a cultured and edible food. This involves methods of cutting, cooking, mixing of ingredients, selecting of ingredients, and adapting of the recipe. The process may be as simple as picking an apple from a tree or taking a handful of raisins from a box to complex and sophisticated techniques requiring refined skills and extensive experience.

Presentation refers to how food is physically arranged and presented for consumption. Presentation can frame the act of eating as a social event and as a meal genre and can also communicate the emotional responses intended to occur. Candlelight implies romance; fine china a formal, celebratory event; paper plates an informal and casual occasion.

Performance includes two aspects. First is the manner in which the food is consumed, the utensils used, and the immediate context: the time and place of consumption and other people present. Performance also refers to the cultural use of food, to the meanings intentionally attached and elicited to the food item or meal, and the occasion for consumption.

Foodways can be performed as symbol in any number of arenas—cookbooks, festivals, restaurants, cooking competitions, family holiday meals. Each of these offer sites for the articulation and manipulation of the meanings of the foodways. Similarly, food symbols occur in a variety of forms: as objects, activities, relationships, events, gestures, and spatial units within a ritual.

Food as a symbol can refer to any aspect of a culture's or individual's history and identity. Commonly recognized and articulated referential domains include ethnicity, region, gender, religion, ethos, social status, and social relationships

Ethnicity is one of the most common references for food. These foods become symbolic frequently because they stand in contrast to host foods and mark the ethnic group as different and separate. This marking is frequently, though not always, negative, emphasizing the strangeness of the ethnic group, and the particular foods

Food has always served as a potent symbol of identity, religious preference, festivities, even nationalism. This 1907 postcard celebrates apple pie as the ultimate symbol of American patriotism. ROUGHWOOD COLLECTION.

functioning as symbols depend on the specific cultural context of that group.

Foods may also become symbolic of ethnicity because of their ubiquitousness in the cuisine of that ethnic group—rice in Asian cultures, beans and tortillas in Mexican cuisine, curry spices in Indian cuisine. Through their consistent use, these foods become associated with that identity; however, they may or may not be felt by members of that ethnic group to symbolize their heritage. Symbols of ethnicity are frequently ascribed by primary cultures or institutions.

Food can be used to refer to another ethnic group, frequently in a derogatory manner—French are called “frogs,” Germans “krauts.” Again, the food used as symbol represents the difference between two cultures and is often an item considered inedible, or at least, unpalatable

to one culture, stigmatizing the other as less civilized or even less human.

Region is another major referential domain of food. As with ethnicity, regional foods are frequently those that stand in contrast to foods found in other regions, therefore marking differences rather than representing the culture. American regional food symbols include grits for the South, lobsters for Maine, cheese for Wisconsin, meat and potatoes for the Midwest. Region and ethnicity can be closely connected. For example, much historical Southern cooking is derived from African American traditions; the upper Midwest is closely associated with Scandinavian foods.

Religion and ethos are emotionally powerful references for food, representing individuals' and cultures' worldviews and value systems. Some food symbols invoke an entire foodways system and its underlying ethos: Kosher foods embody Judaism; meatless meals reference vegetarianism; diet foods may represent a status-quo valuing of physical appearance and traditional gender roles. Specific foods may also symbolize ritual acts or occasions within a belief system: bread and wine represent the body and blood of Christ and the ritual of communion in Christianity.

Gender is another referential domain, with some cultures designating particular foods as symbolizing specific genders and maintaining strict taboos to ensure social and psychological distance between genders. Other cultures demonstrate less formalized perspectives; having stereotypes rather than taboos. In the United States, large portions of any food, thick slabs of meat, beer, and "hearty" foods are associated with masculinity, while foods thought to be light—salads, quiche, poultry, and fish—are associated with femaleness.

Food as symbolic of social relationships includes status and place within a social group as well as relationships between individuals. Food can be used to mark one's socioeconomic standing, since certain items are associated with particular classes: for example, caviar, fine wine, and gourmet cooking with upper classes; beer, white bread, and junk food with lower classes. Some foods, such as hot dogs, apple pie, chili, and barbecue, cut across class divisions and are sometimes used to intentionally signify a democratic and "all-American" event or institution.

Individuals can also use food as social capital, in that by demonstrating competence with a particular food, they demonstrate a mastery of knowledge needed to belong to a particular social group. For example, being able to discern quality of wine can signify membership in an upper class; being able to ingest extremely spicy peppers can signify masculinity. Food can also be used to signify relationships between individuals. The referential meaning, however, is situational and frequently tied to celebrations or rituals. A box of chocolates often represents romance, particularly on Valentine's Day; however, it can also be a gesture of thanks for hospitality.

Overall, food is a rich resource for symbolic communication, expression, and action.

**SYRUPS.** Syrup is essentially sugar dissolved in water, with or without flavors. Candy making relies almost exclusively on the special qualities of hot sugar syrups. Other foods which use them as ingredients are ice creams, baked items, drinks, and preserved fruit.

Maple syrup, made in eastern Canada and in the northeastern part of the United States, is a special product, made by boiling down sap from maple trees. It is made in early spring, and the special flavor of this product is much appreciated on pancakes and waffles and in frostings, desserts, and candies. Other countries also make syrups from fruit juices or tree sap. Grape juice syrup is known as *pekmez* in Turkey and *dibs* in the Arabian Gulf states (*dibs* can also be based on date juice). Pomegranate juice is boiled down to make syrup for drinks and cooking in Syria, Iran, and neighboring areas, and carob pod syrup is used in Cyprus, Lebanon, and Asia Minor. Honey, although regarded as a different commodity entirely because of the production method, is chemically related to syrups and shares similar characteristics.

In some countries, residues from sugar refining are called syrup, notably Golden Syrup, a branded product sold in the United Kingdom. It has a blander flavor than molasses and is a light gold color. In China and Japan, rice is mixed with malt, whose enzymes break down starch from the grain to give sugar. Corn syrup, produced from maize by a similar method, is an industrial product, important in candy, baking, and drinks manufacture.

#### Sugar Syrup

Sugar syrups are simple to make but have no agreed formula. Cooks and pastry chefs prepare "stock syrup" us-

ing the proportions of sugar to water that are demanded by specific recipes. A basic formula is five cups sugar to four cups water (one kilo to one liter). The two are stirred together until dissolved, brought to the boil, then cooled and refrigerated. Old recipes sometimes call for “light syrup” or “heavy syrup”; only experiment shows what quantities are best. This hit-and-miss system is inadequate for industry, so methods for measuring syrup density (and therefore its sugar content and properties in food) have been devised. The saccharometer, a weighted glass bulb that floats upright in the syrup so that a figure can be read off a scale, has been used since the early nineteenth century. Two types of scale—degrees Baumé (devised by the French chemist Antoine Baumé, 1728–1804) and a modern decimal system—are used. Special thermometers were devised for candy makers in the late nineteenth century. Modern industry relies on more complex devices.

### Maple Syrup

This runny brown syrup with a wonderful flavor is produced from the sap of various maple species, especially the hard or rock maple, *Acer saccharum*, and the black maple, *Acer nigrum*. The trees are tapped in early spring when the sap runs in large quantities, especially after a very cold winter and when there are relatively high daytime temperatures and cold nights. A small hole is bored in each trunk and fitted with a spout; the sap is collected in buckets underneath. Several gallons can be collected from a tree without damaging it.

Maple sap contains about 3 percent naturally occurring sugar (sucrose). The accumulated sap is concentrated by boiling until the sucrose content is about 62 percent. It takes between thirty and forty gallons of sap to produce a gallon of syrup. The heating process leads to reactions between the sucrose and amino acids contained in the sap, which produces the color and unique flavor of the syrup. Until the late nineteenth century, the sap was concentrated to a point at which it would form crystals of sugar. This has left a legacy of terms such as “sugar house,” “sugar bush,” and “sugaring off” that are still in use. However, most production is now aimed at making syrup and maple candy.

Native Americans had their own methods for making maple syrup since they had only flammable birch bark or fragile clay vessels. One method they used for concentrating the sap was heating it with hot stones. Another was allowing it to freeze so that some of the water could be lifted off the top as a block of pure ice, leaving syrup with a higher sugar concentration. European settlers introduced metal kettles, which made boiling easier.

Pure maple syrup has an excellent flavor but is expensive because production is affected by the weather, and it is a labor-intensive cottage industry. Several grades varying in flavor and color are produced, and pale syrup is considered the best quality. The containers bear a controlled symbol of a maple leaf as a guarantee. “Maple-

flavored syrup,” made by stretching a little true maple syrup with corn syrup, is much cheaper.

Maple syrup is considered very much a North American product, but there were old-world precedents for the idea. Birch sap was collected and used in parts of Europe to make syrup or alternatively, fermented to make “wine.” In the Middle East and India, the sap of date palms is still used to make syrup and sugar.

### Corn Syrup

Corn syrup is produced by soaking maize kernels. This extracts the starch, which consists of long chains of glucose molecules. Acid or an enzyme is used to break the starch down into shorter lengths, including maltose (the sugar which provides sweetness in malt, two glucose units linked together) and individual glucose molecules. The process can be halted at different stages to give a thick texture (many long chains of glucose molecules) or a sweeter one (more individual molecules); taste and texture can therefore be tailored to the needs of the food industry.

Another enzyme is used to “invert” the glucose to become fructose for high-fructose corn syrup. This has an identical chemical formula but a different molecular structure and tastes intensely sweet. The process is called inversion because glucose rotates a beam of polarized light to the right (hence its alternative name of dextrose), whilst fructose (also known as levulose) rotates it to the left.

Thick corn syrups are much used in candy making because their long-chain molecules help to inhibit the formation of crystals in soft candies without making them overly sweet. Fructose syrups, significantly cheaper than ordinary sugar and more convenient to use, are increasingly important in the soft drinks industry. Other uses for corn syrups include cakes, cookies, pie fillings, jellies, and various composite food products.

The process for making corn syrup is known as hydrolysis. It was discovered by the German-Russian chemist K. S. Kirchhof in 1811 when he heated potato starch in the presence of sulfuric acid and found that it yielded sweet crystals and a syrup. The technique was developed into an industrial process. In 1865 the Union Sugar Company of New York began manufacturing corn syrup.

### Uses of Syrup

Syrups of sugar and fruit juice or other essences are used to make drinks and are diluted as required at home or in bulk to make branded drinks at a bottling plant. This use echoes the origin of the word “syrup.” It is derived from the Arabic *sharab*, which originally meant a sweet drink (“sherbet” also comes from this root). Simple sugar syrup is an important ingredient in other drinks such as juleps, a word that has an equally exotic derivation from the Persian *golab*, meaning rosewater. Fruit syrups are also used as dessert sauces and, when poured over crushed ice in a paper cone, are essential to that summer favorite, the snow cone.

Concentrated syrups are much used in cooking and preserving fruit. They add a sweet flavor and inhibit the growth of spoilage microorganisms. Weak syrups sweeten fruit salads and compotes. Stronger ones are used in canning although concerns about excessive sugar consumption led to the substitution of fruit juices in the late twentieth century. Fruit is candied or crystallized by steeping it in increasingly concentrated syrups. Starting with a light syrup, osmosis allows the sugar to penetrate the cells of the fruit. The syrup strength is concentrated progressively over several days until enough sugar has been absorbed to prevent the fruit from rotting. This technique was brought to North America by the earliest European settlers. Compotes and candied fruit represent a cooking and preserving spectrum which goes back to medieval Europe.

The chemical and physical properties of syrups make them exceptionally useful in industrial baking. Many syrups are hygroscopic, that is, they attract water. Because of this, corn syrup is added to cakes and cookies, where it softens the texture and extends shelf-life. Honey has long been used in this way, for example, in *Lebkuchen*, the traditional German gingerbread.

Many cultures use syrups in traditional baking. The English use sugar syrup to glaze the hot cross buns made for Good Friday and put golden syrup into treacle tarts, distant relations of shoofly pies, which are made with molasses. Babas, small rich yeast cakes of eastern European origin, are soaked in rum-flavored syrup. In the eastern Mediterranean and the Middle East, many pastries require syrup as a sweetener. A well-known example is baklava, made of layers of thin pastry with a nut filling, over which syrup is poured after baking (sugar syrup sometimes substitutes for the traditional honey). *Jellabies* (also *jalebi*), deep-fried batter spirals widely made in the Middle East, and *gulab jamun*, Indian confections of flour

and reduced milk, are sweetened and stored in syrup. Chinese and Japanese cultures use malt syrup in traditional desserts and candies.

Nutritionally, syrups provide concentrated energy but little else. They also tend to be used in energy-dense foods such as candies, desserts, and baked goods, all of which are considered undesirable for good health in large quantities. Diets high in sugars and other carbohydrates are also less likely to be high in essential nutrients. Particular worries are expressed by nutritionists over soft drinks. They are consumed in large amounts by certain sectors of the population in the developed world, and they are thought to be especially bad for the teeth. However, the food and drink industries consider syrups of enormous value in enhancing the flavor and texture in numerous foods and drinks. Corn syrup in particular is simple to use and relatively cheap, so it is likely that syrups will continue to be used in large quantities.

**TABLE DÉCOR.** *See* Presentation of Food; Styling of Food.

**TABLE MANNERS.** *See* Etiquette and Eating Habits; Table Talk.

**TABLE TALK.** All human societies take advantage of the fact that meals are physically necessary, normally frequent, and often eaten with others. They turn dinnertimes into opportunities to express and to practice “culture.” Because talking is the primary mode of human communication, mealtimes commonly provide occasions for conversation. Every culture has its own ideas about the management of verbal interaction or of silence at meals.

#### When to Talk

Most of the time human beings who are sharing a meal prefer to eat without saying much. They simply concentrate on what they are doing, appreciating and enjoying their food. When talking takes place, it is often socially regulated, its timing clarified by rules. In some societies talk is completed before dinner. The meal then serves as a contented celebration of togetherness and agreement, after the discussions that have preceded it (Ortner, 1978; Fitzgerald, 1941). In others the eating comes first, and only when hunger is satisfied should talk break out (Chao, 1956). Formal meals might require silence, conversation being reserved for intimacy among family and friends (Toffin, 1977, ch. 4). In modern Europe and North America the opposite is the case. On formal occasions or when invited out, people should talk; it is rude not to. For this very reason eating together in “companionable” silence can be a sign of great intimacy. On the other hand, everybody eating without talking might be the expression of an oppressive tension.

The Japanese begin a banquet in silence but warm up as time goes on. Barriers fall, and discourse increases accordingly (Befu, 1974). Sometimes it is thought proper that only elders and important people should speak (Okere, 1983). Although it is commonly accepted that mealtimes are excellent opportunities for small children to learn to talk, in many places and times older children

have been forbidden to speak during meals taken with adults. In the modern West, middle-class children are likely to be encouraged to talk during meals. Such family meals have even been described as “class[es] in oral expression” (Bossard and Boll, 1966, p. 141).

Until the early twentieth century in the United States and until the late twentieth century in Britain, it was thought proper at formal upper-class meals to send the women away from the dining room table into the drawing room, originally called a “withdrawing” room, owing to this practice. They took tea and engaged in conversation, leaving the men behind to move together around the table to drink port and discuss politics and other “male” subjects. (The men had been separated during the meal owing to “promiscuous” seating, men and women alternating around the table.) The host decided when the segregation should cease and then shepherded the men to “join the ladies” again (Post, 1922, pp. 223–224).

Often entertainment is laid on, and then of course talking is minimal. Watching television during meals is a modern instance of an ancient tradition that includes entertainers dancing and juggling during pauses between courses (as in the medieval and Renaissance *entremets*), someone reading aloud as monks eat silently in the refectory, musicians performing, and even the host dancing, singing, or playing a musical instrument for his or her guests.

#### Drama and Dialogue

At aristocratic ancient Greek dinner parties, talk was mostly limited, during the actual eating, to reaching a decision about what subjects to discuss afterward. Later the wine drinking began, the *symposion* or “drinking together,” and then people were expected to be able to sing in turn and to have something intelligent to say about the topics proposed. From this custom a literary genre developed in which an imaginary dialogue after dinner is reported by the author. Plato’s *Symposium* (on the subject “What is love?”), Xenophon’s *Symposium*, Plutarch’s *Symposiacs* and *Banquet of the Seven Sages*, Macrobius’s *Saturnalia*, and Athenaeus’s fifteen-volume *The Sophists at Dinner* are surviving examples of the type. They are ancestors of collections of table talk or *propos de table* that

have continued as a minor tradition of European and American belles lettres down the centuries.

Meals have often been the locus of drama, the eating companions filling the roles of both actors and audience. Every organized feast has a theatrical aspect, and what is said on the occasion is at least as memorable as what is eaten or what is done. Where it is that people sit (and therefore who will most easily talk to whom) is often decided by the host, the “producer” of the performance. In many cultures it is incumbent upon the host before, during, or after the meal to give a speech. Dramatic rituals requiring speech have often been inserted into mealtime festivity. One highly developed and still surviving custom in this class is that of drinking toasts with the eloquence traditionally required (Dickson, 1981). In medieval Europe a rich feast was incomplete without a nonpartaking audience looking on.

All religions include ritual eating events, usually with important speaking roles for those present. Examples are the Jewish seder (Quesnel et al., 1999, pt. 1) or the Javanese *slametan* (Geertz, 1960). During the last supper that Jesus ate with his friends, he instituted the Eucharist and asked that his disciples repeat his words and actions. In the course of the meal his betrayer was revealed. The discourses of Jesus during this meal are of central importance to Christian belief (John 13–17; Luke 22). Prayer, either before meals, or after meals, or both, is common the world over.

### Rules of Behavior

Modern Western societies make talking an important component of a formal meal and of many other eating events as well. (These very societies have rigid requirements about eating silently, with mouths shut. The necessity of nevertheless talking constitutes the kind of complication that is typical of manners in general.) Where people talk, everybody should do so. Not talking is not joining in, where conviviality is the aim. The silence of one individual in these cultures and in others can be interpreted as hostility, incompetence, or even greed, a plot to take advantage of the others’ conversation in order to eat more than anybody else.

It is forbidden at a dining room table to reach past people, and especially across their plates, for what one might need. It is therefore necessary to ask and then to thank the neighbor who obliges. Before helping himself or herself to more food, the polite diner first asks others whether they want some more. Such simple exchanges, made mandatory by table manners, create a ready-made, basic fabric of verbal interaction with others.

Since all have the duty, all should also have the opportunity to talk. Politeness therefore commonly demands, to varying degrees in different cultures, no drowning out of others’ words by shouting and no interrupting. All the manners governing conversation may apply even more strictly than is usual. Where the guests are seated around a table, on view to all those present, it

### GOOD MANNERS

Let Noise of lewd Disputes be quite forborn,  
No Maudlin Lovers here in Corners Mourn,  
But all be Brisk, and Talk, but not too much.  
On Sacred things, Let none presume to touch,  
Nor Profane Scripture, or sawcily wrong  
Affairs of State with an Irreverent Tongue.  
Let Mirth be Innocent, and each man see  
That all his Jests without Reflection be.  
(*The Rules and Orders of the Coffee House*, 1674)

The turning of the table is accomplished by the hostess, who merely turns from the gentleman (on her left probably) with whom she has been talking through the soup and the fish course, to the one on her right. As she turns, the lady to whom the “right” gentleman has been talking, turns to the gentleman further on, and in a moment everyone at table is talking to a new neighbor. [To refuse to change partners is to cause the whole table to be blocked,] leaving one lady and one gentleman on either side of the block, staring alone at their plates. At this point the hostess has to come to the rescue by attracting the blocking lady’s attention and saying, “Sally, you cannot talk to Professor Bugge any longer! Mr. Smith has been trying his best to attract your attention.” (Emily Post, 1922, p. 221)

I knew a man who had a story about a Gun, which he thought a good one and that he told it very well; he tried all means in the world to turn the conversation upon Guns—but if he failed in his attempt, he started in his chair, and said he heard a Gun fired, but when the company assured him that they heard no such thing, he answered, perhaps then I am mistaken, but however, since we are talking of Guns,—and then told his story, to the great indignation of the company. (Lord Chesterfield, Letter to his Godson, no. 141)

is bad manners to talk, whisper, and laugh with one companion to the exclusion and possible covert ridicule of others. A guest should not be singled out and so closely questioned that he or she has no time to eat the food.

It is rude, the etiquette books repeatedly remind their readers, to upset people with descriptions of what might disgust them or shock them (the last thing people want while eating is to be perturbed or “put off their food”). Dinnertime conversationalists are often advised against controversial or overly important subjects like politics or religion. Talking shop is frowned upon and also long-winded technical explanations nobody wants to hear. There should be no holding forth so that only one person is heard from. The host in particular is enjoined not to praise the culinary excellence of the meal or oth-

erwise to put himself or herself forward. He or she should concentrate instead on encouraging the guests to shine (Morel, 1977; Staffe, 1899).

At a Japanese *cha no yu* or tea ceremony, the host goes to great trouble to make the dining space beautiful with flower arrangements and utensils chosen to express appreciation for the season of the year. The host might deliberately and delicately absent himself at a certain point to give guests the opportunity to comment, without embarrassing the host with too much praise, on the tea bowls, their beauty and their perfect taste, and the room and its furnishings. Contemplation, heightened sensitivity, and admiration are the aim of the ceremony. Spoken expression of people's responses is an essential aspect of the experience (Kondo, 1985).

### Wit, Creativity, Social Bonding

Among people prosperous enough to eat in company for pleasure and entertainment, meals have often been occasions for the display of wit. Brilliant conversation was what writers of "table talk" attempted to recapture. Table talk is different with every gathering; it is on each occasion the group's own improvised creation. The conversation may range from the boring or unpleasant to a memorable art form, as may the preparation of the meal itself. At times dinnertime discourse can become artificial and competitive and even part of power struggles, since being invited to the right dinner parties and so consorting with important people has often been essential to an ambitious career. Dinner guests invited in order to dazzle others with their famous wit have frequently prepared themselves with stories ready to insert into the conversation, have sharpened their sallies in advance, and have polished their bons mots and their paradoxes.

Dinnertime conversation of course takes time. This has often meant that it was, as a social skill, highly developed only among people with money, leisure, and servants as well as verbal polish. In modern society, where time is money or "at a premium," table conversation may be forced into a minor role in people's lives. Yet it is often still customary for people to make time for talking at meals. Conversation after dinner is an institution in Hispanic cultures, with its own name, *hacer la sobremesa*, "doing the over-the-table" or "doing the tablecloth." The dishes are removed for this part of the event. Such conversations knit families and groups of friends together, ensuring contact, constant negotiation, and understanding. They are important occasions for identity building and for self-expression.

"It's not what's on the table that matters but what's on the chairs." The adage expresses what has been an almost universal insistence among human beings, that we people should strive not to let the material necessities dominate our their lives, that the food should not be the only attraction when we people sit down to eat together.

### PLUTARCH'S SYMPOSIACS

Examples of subjects for discussion at a symposium:

- "Whether the host should arrange the placing of his guests or leave it to the guests themselves."
- "Why men become hungrier in autumn."
- "Why we take pleasure in hearing actors represent anger and pain but not in seeing people actually experience those emotions."

**TABOOS.** A food taboo is a prohibition against consuming certain foods. The word “taboo” (also spelled “tabu”) is Polynesian and means ‘sacred’ or ‘forbidden’; it has a quasi-magical or religious overtone. The term was introduced in the anthropological literature in the second half of the nineteenth century. In the field of food and nutrition, food taboos are not necessarily connected with magical-religious practices, and some nutritionists prefer to speak of “food avoidance.” In this article these terms are used interchangeably.

Food is a culturally specific concept. In general, anything can function as food if it is not immediately toxic. But what is edible in one culture may not be in another. The concept of food is determined by three factors: biology, geography, and culture. Certain plants and animals are not consumed because they are indigestible. Geography also plays a role. For example, dairy products are not part of the food culture of the humid tropical regions since the geographical conditions for keeping cattle are unfavorable. Milk is often a taboo food in such cultures. Insects are not considered food in Europe and most of the United States despite attempts to introduce them in the late twentieth century. This is because there are few edible insects in regions with temperate climates. In Mexico, by contrast, insects are packaged in plastic sachets, cans, or jars for sale. Cultural reasons for food taboos often have a geographical basis—unknown or exotic foods will be rejected as unfit for consumption.

It is of interest to note that food avoidance most frequently relates to animal meat, since in most cultures human beings have an emotional relationship with animals they have to kill to eat. One of the few taboos of a food of vegetable origin is the prohibition against alcohol for Muslims and some Christian denominations.

Food may establish a cultural identity of an ethnic group, religion, or nation. Food taboos in a society function also as a means to show differences between various groups and strengthen their cultural identity. Refraining

from eating pork is not only a question of religious identity but is likewise an indication of whether or not one belongs to the Jewish or Muslim cultural community. In order to better understand the range of food taboos, it is useful to distinguish between permanent and temporary food taboos or food avoidances.

### Permanent Food Taboos

Foods that are permanent taboos or avoidances are always prohibited for a specific group. The classic example of a permanent food taboo is the prohibition against pork by Jews and Muslims. The Jewish prohibition against pork is found in Leviticus 11:1. Some anthropologists point out that food taboos are based on the failure of these foods to fit into the usual systems of classification. Foods that do not fit into these classifications are unsuitable for consumption, or unclean. According to the Qur'an (2, 168), Muslims should not only avoid pork, but also blood, non-ritually slaughtered animals, and cadavers and alcohol. In the case of both Jewish and Muslim food taboos, the foods themselves are considered unclean. A different concept of food avoidance is found in Hinduism. Hindus abstain from eating beef because cows are considered sacred. Various arguments have been used to explain the origins of such food taboos or food avoidance including religion, culture, and hygiene.

Marvin Harris has rightly pointed out that when people reject certain foods, there must be a logical and economical reason for doing so. The pig is an animal of sedentary farmers and unfit for a pastoral way of life because pigs cannot be herded over long distances without suffering a high rate of mortality. Herdsmen generally despise the lifestyle of sedentary farming communities.

In Western society cats and dogs are not consumed because of the emotional relationships developed with these pets. Increasingly pets are being “humanized” in such a way that eating them is seen as an act of anthropophagy or cannibalism. The feeling of closeness to certain animals can also be found in the savannah regions of West Africa. Certain West African clans consider dogs clan animals, based on the fact that they have been beneficial to the clan in the past; as clan animals they are unfit for consumption. Hippocrates (460–377 B.C.E.) regarded dog meat favorably as a light meal, but in later antiquity, dogs were considered unclean and unfit to eat. This is still the case in the Mediterranean area and the Middle East. By contrast, dog meat is popular in China and the mountainous regions of the Philippines. From a nutritional point of view, dog meat is an excellent source of animal protein, and dogs do not require the grazing area demanded by cattle or other large ruminants.

### Temporary Food Taboos or Avoidances

Some foods are avoided for certain periods of time. These restrictions often apply to women and relate to the reproduction cycle.

The times of temporary food avoidances related to particular periods of the life cycle include:

- Pregnancy
- Birth
- Lactation
- Infancy
- Initiation
- Periods of illness or sickness

From a nutritional point of view, temporary food avoidances are of great importance as they concern vulnerable groups: pregnant women, breast-feeding women, and infants and children during the period of weaning and growth. Food regulations and avoidances during these periods often deprive the individual of nutritionally valuable foods such as meat, fish, eggs, or vegetables. In a number of African countries pregnant women avoid green vegetables. They also do not consume fish. When asked why, women say the unborn child might develop a head shaped like that of a fish. Some of these avoidances may seem odd from a scientific point of view, but there is often an unnoticed logic behind it. In the first place, women are aware of the critical period and know that much has to be done to ensure the successful delivery of a healthy child. Observing the rules of avoidance will give her the strength of knowing that everything possible has been done for the benefit of the child.

In Central Africa nutritionists observed that young children did not eat eggs. They were worried that a nutritious food was not available for this vulnerable group. The village elders gave a convincing explanation of why eggs should be avoided by children. In the past the wise ancestors were much concerned about young children roaming around the villages searching for eggs and even chasing the brood hens away from their eggs. In order to avoid a depletion of the poultry stock, the elderly decided that eggs were harmful to young children and should be avoided.

A different form of temporary food avoidances involves the rules of fasting. In medieval Christianity the most important period of fasting was Lent (the period from Ash Wednesday to Holy Saturday), during which meat and animal products were forbidden. There were also other days (Ember Days, Fridays, etc.) on which people were required to abstain from eating meat. The Reformation broke the tradition of fasting to a large extent. The Ethiopian Orthodox Church has a wide and complicated system of dietary rules and fasting, as does the Eastern Orthodox Church. In the Muslim world, Ramadan, the ninth month of the Muslim year, means strict fasting, even from beverages, from sunrise to sunset (Sakr).

### **Do Food Taboos Change and Disappear?**

Food taboos may seem rather stable, but they are often under pressure because the society is changing. Migration is a powerful factor in the process of changing food

culture. In Europe and North America, most Muslim migrants from the Middle East and South Asia try to maintain their food habits, but some cannot fully resist the food culture of their new home country. A substantial number of Muslims begin drinking beer, wine, and even stronger spirits. Women tend to be less inclined to give up the avoidance of alcohol. The fear of pollution from pork often remains strong, however. In some European countries Muslims refrain from eating in factory canteens out of fear that meals may be polluted with pork fat or pork meat. In contrast, many Jewish Europeans and Americans eat pork from time to time, or even on a regular basis.

Nutrition and health education have reduced the temporary food avoidances of the vulnerable groups in a great number of countries. In the humid tropical countries of Africa and Asia, where the raising of dairy animals is unfavorable, the rejection of milk as a food is diminishing. Despite the occurrence of lactose intolerance among the population, the use of milk and milk products has extended since colonial times. Primary lactose intolerance occurs from an apparent decrease in the intestinal enzyme lactase and can occur between the ages of two and five years. This condition is present in about 75 percent of the world population. However, small but significant quantities of milk consumed throughout the day can be tolerated among ethnic groups known to be lactose intolerant. At the beginning of the twenty-first century, milk products and a little fresh milk are available for the upper and middle classes. This availability seems to have increased due to dairy exports from Western countries and dairy food aid during the 1950s through the 1970s. In a country without a dairy tradition such as Indonesia, the importation of canned sweetened condensed milk can be traced back to around 1883. In the high lands of Java, the Dutch introduced dairy farming on a small scale in the nineteenth century. From the colonists, a modest use of milk spread gradually among the emerging Indonesian upper and middle classes.

In the United States and other countries with Anglo-Saxon traditions, horsemeat is not part of the food culture. This is in contrast to continental Europe, in particular France, where horsemeat is a well-known and appreciated food. The history of horsemeat gives insight into how attitudes toward food avoidance change over the course of time. In Europe it started with a decree by Pope Gregory III (d. 714) that the Christian communities of Germany and the Low Countries refrain from eating horsemeat because the horse played an important role in pagan rituals. The purpose of the decree was that the Christian community should distinguish itself from the pagans by avoiding a typical pagan symbol, horsemeat. Gradually the consumption of horseflesh disappeared. The meat was considered to be unfit for consumption. In the nineteenth century the attitude toward horsemeat changed dramatically. Food emergencies connected with war and promotion of horsemeat as a food were the

driving forces for change. During the Napoleonic Wars, hungry soldiers were forced to eat their horses. To their surprise, the meat was fit to eat and even had a reasonably good taste. French pharmacists promoted the idea that horsemeat was suitable for consumption, and from a scientific point of view no threat at all to health. Discarded workhorses became a source of good and cheap meat for the growing working classes in urban France. The concept of horsemeat as food spread to other European countries, but not to the United Kingdom, where the horse remained a noble animal, and the idea of eating horsemeat was viewed with disgust.

In periods of emergency, dietary rules including food avoidances can be temporarily ended. The West African Fulani pastoralists avoid the consumption of fish. During the dry season the herdsman have to move with their cattle from the northern savannahs to the land along the Niger River in the south. Because of the seasonal food shortage, herdsman are more or less forced to turn to eating fish. In rural areas with a dry and a rainy season, people will collect in the period of seasonal food shortage the so-called hungry foods. Hungry foods are mainly wild foods, often not very attractive and tasty and as such normally avoided. They are consumed only in an emergency.

**TAILLEVENT.** Taillevent (c. 1315–1395), whose real name was Guillaume Tirel, was employed in the kitchens of the French court from the 1320s to until his death in 1395. The recipes from the manuscript cookbook with which his name is associated, *Le Viandier*, were copied and widely disseminated both during and long after Taillevent's lifetime and had an enormous influence on French cookery, as evidenced by the different versions to be found in various existing manuscripts. Toward the end of the fifteenth century, as the first cookbook to be printed in France, a greatly enlarged version of *Le Viandier* remained in circulation for over a century and had an enormous influence on French cookery. Because of the success of his cookbook, Taillevent can rightfully be called the first chef to achieve "star" status in France, where his name became synonymous with "master chef."

Taillevent's recipes, destined principally for festive occasions, give us a glimpse of the kind of cuisine practiced in the aristocratic households from the fourteenth to the sixteenth century. Characterized by the use of a wide range of spices—in keeping with the dietetic principles of the time that demanded that the cold, wet "humors" of meats, fish, and vegetables be tempered by the hot, dry "virtues" of spices—they call for such familiar ingredients as veal, capon, or pike, as well as much more exotic foods like crane, swan, or sturgeon, prized for the beauty of their feathers (placed back over them to serve), or for their sheer size. Among the new recipes included in the printed *Viandier* at the end of the fifteenth century, the importance of pâtés and tarts in the French culinary landscape is documented for the first time.

**TAKE-OUT FOOD.** Take-out food is food prepared for consumption away from the location where it is purchased. As a term, its first appearance was in James Cain's novel *Mildred Pierce* (1941), in which the main character expressed her desire to sell pies to the take-out

trade. Synonyms for “take-out” include “carry-out,” “take-away,” and “food to go.”

### Origins of Take-out Food

From Roman antiquity onward, people have been buying foods to consume elsewhere that have already undergone some form of preparation. Roman cook shops, early precursors to restaurants, were an early example of today’s modern gourmet to-go shop. A variety of production kitchens were available to the Romans. Not only did the Roman soldiers get food from a centralized kitchen, but large towns such as Rome had areas where food was prepared for eating on the premises or to take out. Cooks in ancient Greece and Rome were often itinerant, bringing their prepared foods to theater audiences, predating ballpark hot-dog vendors by millennia. In ancient Rome, according to historian Maguelonne Tousseint-Samat, prepared foods were available for sale to be consumed in the markets or elsewhere. In fact, Trajan’s Forum in Rome could be viewed as an extension of the idea of the Greek agora, where all kinds of goods were freely exchanged.

Cooked-meat vendors date back to ancient Mesopotamia, where a wide variety of foods were available to take out, from roasted meats to fish to almond paste-based desserts.

The custom of buying ready-cooked food was found, as recorded by historian Reay Tannahill, in twelfth-century London, where

you may find viands, dishes roast, fried and boiled, fish great and small, the coarser flesh for the poor, the more delicate for the rich, such as venison, and birds both big and little. If friends, weary with travel, should of a sudden come to any of the citizens, and it is not their pleasure to wait fasting till fresh food is bought and cooked....they hasten to the river bank, and there all things desirable are ready to their hand (Tannahill, p. 164).

Even in late-sixteenth-century France, more than two hundred years before the term “restaurant” takes on the meaning now associated with it, prepared foods were available from “the roasters and the pastrycooks, [who] in less than an hour, will arrange a dinner for you, or a supper,” to eat on the premises or to take out to consume elsewhere. Only from 1786 onward did Parisian caterers and restaurateurs open their doors to the public for consumption of meals. It was at this time that the custom of the table d’hôte (“host’s table”) took hold, an expression that meant that paying customers were invited to partake of foods in the caterer’s place of business at the very table where the caterer dined, instead of having to take the meal out to eat elsewhere.

Across the English Channel, a hundred years later, fast-food eating shops had become London institutions, frequented by members of all classes. In 1671 in Munich, Germany, the luxury food store Dallmayr opened, purveying box lunches to the noblemen of the day. The tra-

dition continued with the founding of Fortnum and Mason in London in 1707. By 1788 Fortnum’s was selling foods to go, including boned portions of poultry and game in aspic jelly, decorated with lobsters and prawns, all prepared so as to require no cutting, for a distinguished clientele that resided nearby. By 1851 ready-to-eat dishes had become all the rage: to sustain life during such ceremonies as the Coronation festivities, the new queen’s review of 6,000 troops in Hyde Park, and the Great Exhibition of 1851. Harrods in 1849 began purveying high-quality foodstuffs to royalty and upper-class Londoners alike.

Hédiard (founded in 1854) and Fauchon (1886) brought a taste of what were then considered exotic foods to the Parisian elite. The German-born Leonardo Peck opened an epicurean delicatessen in Milan, Italy, in 1883, specializing in artisanally prepared smoked and cured meats and cheeses. The large department store Kaufhaus Des Westens (KaDeWe) in Berlin, Germany, established in 1907, devoted considerable space to foods to go. These and other stores featured imported fruits, spices, teas, and coffee; foods prepared on the premises for take-out set new standards in elegance and luxury that retailers in the United States wished to emulate.

### Packaging

Packaging is an essential component of foods to go. In the United States, paper bags for holding purchases were introduced around the 1860s, a significant development that catalyzed the growth of carry-out foods. Prior to this, clerks had often placed small purchases for customers who were without baskets, bags, or other containers into cones made of rolled paper, twisting them at the bottom to create a kind of primitive bag. By the 1860s the process of making paper containers was becoming mechanized. By 1875, a full-scale manufacture of paper bags was under way. Coupled with stepped-up mechanized production of food, improved refrigeration technology, and transportation of food by rail, a multiplicity of food choices was becoming available nationwide.

The late nineteenth century saw the establishment of grocery store chains. A&P was established in 1869, Kroger in 1882, and Gristede Brothers in 1891. Department store food halls, such as New York City’s Macy’s food department of 1908, would eventually serve as a model for Dean & DeLuca (founded in 1977 in lower Manhattan), a specialty-foods store with boutique-like departments, each of which specialized in a different category of food (cheese, meats, prepared foods, pastries) displayed artfully.

### Convenience and Education

In one of a number of attempts to educate the working class about healthful eating habits, Ellen Richards, a founder of domestic science who was a chemist and the first woman appointed to the faculty at the Massachusetts

Take-out food has been a feature of urban cookery for centuries, but industrialization and mechanization have altered many sectors of this market, especially in the area of fast foods. This is a scene from McDonald's in Moscow. © AP/WIDE WORLD PHOTOS.

Institute of Technology (1884), helped open the New England Kitchen in 1894 as a place where neighborhood people could purchase foods to take home. Through it, she intended to promote the values of home and family life over the trend toward eating out. Ahead of its time, Richards's effort could be seen as the precursor to the delivery of prepared meals by the then new automobile. In the early 1900s, food delivery services in New Jersey (an offshoot of a communal dining experiment) and Illinois lasted only a few years but served as early models for the pizza delivery services that dominated the take-out food market from the 1970s onward. In the period after World War I, small independently owned grocery stores sprung up in cities and in their surrounding bedroom communities throughout the country, offering prepared foods to the carriage trade. One such operation, William Poll in New York City, started out as a grocery and catering establishment in 1921. Offering some of the earliest prepared take-out of the modern era (1951), a marvel of freezer and packaging technology in the form of shish kebab, cooked and ready for reheating, Poll continued into the twenty-first century. In 1934 the Zabar family started what was to become one of the largest delicatessen-prepared food establishments in New York City; its take-out operations have continued to the present.

In the modern era of food retailing, from the 1960s onward, in the United States the rise of two-career couples created a demand for fast food and prepared foods, available for take-out or delivery. Those early revolutionaries of the Boston experiment such as Ellen Richards, who said that home cooking as traditionally defined would soon be a thing of the past, were more prescient than they may have realized, given how much modern industrialized society has come to depend on sources for ready-to-eat food outside of the home. Among the upwardly mobile and working-class alike, a once weekly pilgrimage to the local Chinese restaurant, a phenomenon

begun in the 1950s, defined take-out for many Americans. The growing ethnic diversity of populations nationwide in the succeeding fifty years enabled Americans to experience the cuisines of other countries, including Mexico, Thailand, Vietnam, and the Middle East. Restaurants with limited seating often capitalized on the demand for convenience and offered their complete menus "to go." Take-out food was no longer limited to pizza, burgers, or fried chicken. From the late 1980s, the percentage of take-out foods purchased increased year by year. Take-out and delivery of foods accounted for 57 percent of all restaurant traffic, with more than nine out of ten table-service restaurants offering take-out options. In the last three decades of the twentieth century, Americans strayed far from the nightly ritual of eating a home-cooked meal with all members of the family congregating around the dinner table. In 2001, according to the National Restaurant Association, 47 percent of Americans aged eighteen to twenty-four said purchasing take-out food is essential to the way they live, with 29 percent of all age groups in agreement. With convenience and variety in increasing demand, the trend is not likely to cease.

#### TEA.

*This entry includes two subentries:*  
Tea as an Icon Food  
Tea (Meal)

#### TEA AS AN ICON FOOD

The origins of tea drinking are shrouded in historical obscurity and legend. While some scholars maintain that tea drinking began in ancient India, most place its be-

ginnings in China as early as 2700 to 3000 B.C.E. A commonly cited account is more recent, however (Qin dynasty, c. 221–206 B.C.E.). According to the story, tea was created one day when the Emperor Shen Nung was boiling water next to a fragrant bush when a gentle breeze blew a leaf from the bush into the pot, creating a pleasing aroma—and tea. Although this story is probably apocryphal, it is likely that plain boiled water or rice water were most commonly drunk in ancient China, and that tea was used occasionally and boiled in combination with other ingredients such as ginger, shallots, orange peel, and mint. The first documented reference to tea occurs in a Chinese dictionary, in 350 B.C.E.

More important than any exact date, however, is the idea of tea as a linchpin and iconic food type in Chinese and other Asian and world cultures. Tea has had social, medicinal, economic, political, and class implications for centuries, being used as a chew, a beverage, a vehicle for familial and business bonding, a curative, a preventative, a stimulant, and a soporific. The preferred drink of many nation's ruling classes, and a measure of economic prosperity among all classes, it is also associated with the British opium trade and the Opium Wars in China, the economic development of the Indian subcontinent and the North American continent, and the beginnings of the American Revolution.

### Tea and Chinese Culture

Published accounts of tea cultivation and enjoyment surfaced in the sixth century B.C.E. when Lao-tzu (c. 604–520 B.C.E.), author of the *Tao Te Ching* and founder of Taoism, is reputed to have proclaimed tea an “elixir of immortality.” That description is supported by tales of a monk who extended his lifespan considerably by drinking forty cups of tea a day. While Chinese drink the beverage with meals and at numerous other points throughout the day, consistent with a culture deeply committed to an ideal life of balanced opposites, they also recommend against drinking too much because overindulgence might have negative effects.

Factual accounts of tea as a bona fide drink surface most convincingly in China during the Han dynasty (c. 206 B.C.E. to 220 C.E.), when it became a widely popular drink, and lacquered cups, manufactured specifically for the use of tea (“tea cups”), appeared. Tea has continued to be popular in China throughout its history, but most notably during a high point of Chinese civilization, the Tang dynasty (c. 618–907 C.E.). During this period, the rituals of tea preparation and drinking were codified and spread throughout northern China and Asia, along with other aspects of China's culture. Tea was also taxed during this period, eventually becoming a valuable asset in Chinese households, where it was used as currency and referred to as “green gold.” Tea bricks (compressed tea leaves) were used to buy horses (and, for example, in the case of the British, were exchanged only for precious metals such as silver and later for opium).

Preparing tea from a samovar, Baghdad, Iraq, circa 1920. The tea is drunk hot from small glasses. ROUGHWOOD COLLECTION.

During the same period, the poet and philosopher Lu Yü (d. 804 C.E.) wrote the *Ch'a Ching* (c. 780 C.E.; later translated as *The Classic of Tea*). Respected among tea enthusiasts, connoisseurs, and amateurs alike it became a definitive book on the subject. Concisely and beautifully written, it describes various forms and types of tea, explaining the selection and use of proper utensils, and discussing the water used for brewing. Water collected from natural springs located near Buddhist monasteries was believed to possess spiritual qualities, for example. Lu Yü also recommended water from the mouth of Szechuan's Yangtze River (where some of the best teas in China are cultivated) and mountain water. The precise instructions of Lu Yü raised tea drinking to an art form, earning him the status of tea “divinity.” It is likely that his *C'ha Ching* became the basis for the highly ritualized and formal Japanese *chado* (“tea ceremony”). Tea-houses were also established during the Tang dynasty, where people could enjoy pungent bitter tea with savory and sweet bite-size morsels or dumplings, early snack foods. (The popular Chinese expression *yam cha* literally means “drink tea,” but figuratively it refers to eating *dim sum* [“touch of the heart”], steamed or fried dumplings stuffed with a variety of fillings, for example, bean paste.)

Two women perform a tea ceremony in a traditional home in Kyoto, Japan. © CATHERINE KARNOW/CORBIS.

The appearance of teahouses further ritualized tea drinking as an essential component of Chinese life, connecting it to business negotiations, social encounters, relaxation, and other facets of Chinese culture. In this sense, it parallels the use of alcohol and other stimulants as social lubricants in other cultures. Tea is also a preferred drink at wedding banquets, and is traditionally presented to the bride and groom as a symbol of unification. Additionally, tea, along with fruit, is used as an offering at ancestral altars. It is also customary, if not mandatory, in Chinese culture to offer a cup of tea to a guest at any time of the day.

### Tea in Japan

While the date of tea's introduction to Japan is difficult to pinpoint, Okakura Kakuzo, the great twentieth-century Japanese philosopher and tea master, wrote that the Japanese Emperor Shomu (c. eighth century C.E.) offered tea brewed from Chinese leaves sent by Japanese ambassadors to the Tang court to one hundred monks. The Japanese monk Saicho (767–822 C.E.), who had spent time in China, is believed to have offered a cup of tea to the Emperor Saga in 815 C.E. Saga was said to be so fond of the drink that he ordered the planting of a bush in order to establish tea as the beverage of choice

in Japan. The tea proved to be too strong for many Japanese, however, and its popularity has proven less consistent than with the Chinese. Nonetheless, Japanese tea cultivation began during this period and was well established by the thirteenth century C.E.

Revivals of interest occurred during the thirteenth century, and reached a plateau during the sixteenth century (a period of cultural consolidation and political reunification), when tea cultivation spread, making the drink widely available. With this cultural shift came the traditional teahouse, a small bamboo hut created by tea master Sen Rikyu, who developed the *chado* (*cha-no-yu*, “hot water for tea”), or tea ceremony. The Japanese came to consider tea a way of life, and, like the Chinese, saw it as a symbol of hospitality, relaxation, and consolation. The *chado* both reflected and extended the preparation and drinking of tea as a ritual, codifying the preparation, serving, and drinking of tea according to strict rules. This codification is sometimes tellingly referred to as “the law of tea,” and is closely associated with the principles of Japanese Zen Buddhism.

The Japanese ceremony involves the whipping and frothing of powdered green tea (*matcha*) with a slit bamboo brush while introducing hot water. It derives from a

## JAPANESE TEA CEREMONY

The rituals known collectively as the Japanese tea ceremony are based on practices brought to Japan from China by Zen priests in the 1200s. Their style of tea preparation became popular among military and merchant elites, and these practices were later codified by Sen no Rikyū (1521–1591). The art is organized by “schools,” such as Ura-senke and Omote-senke.

Finely powdered green tea is put in a bowl, hot water is added, and the tea is whipped into a suspension with a bamboo whisk. The tea is prepared by a host for guests, who are expected to know the elaborate etiquette. For the first several years, students tend to focus on performance aspects, learning when to bow or how to carry utensils into the room. For elite practitioners, however, the key to the art lies in their connoisseurship of the many art pieces used in the ritual, such as the tea bowl, the hanging calligraphy, or the lacquered tea container. Hosts manipulate the symbolism of utensils to create complex themes for each gathering, and guests are expected to read these allusions.

The most complex ritual, called *chaji*, lasts four or more hours and involves the serving of an elaborate meal. The food should be simple and seasonal yet arranged with casual artistry on understated, elegant dishes. After the meal, sake is served. Moist sweets (*omogashi*) are served before the preparation of thick tea (*koicha*) and dried sweets (*o-higashi*) before the preparation of the thin tea (*usucha*).

Chinese Sung Dynasty (c. 960–1279 C.E.) tradition in which steamed and formed tea cakes are pounded into a fine powder. (The Japanese serve *kaiseki-ryōri*, a meal masterfully prepared and eaten prior to the tea ceremony.) Due to its rather complex preparation, *matcha* is

usually reserved for tea ceremonies or special occasions. Japanese *sencha*, loose tea leaves, was brought from China during the seventeenth century, and remains a more convenient and common form of tea. While the tea’s popularity eventually waned, it was revived in the twentieth century, and the Japanese people have come to perceive it as a convenience food, ideally suited to their fast-paced lifestyle, something to accompany a light meal carried in a Japanese lunch box.

### Tea and Europeans

While the Portuguese were the first Europeans to trade and drink Chinese tea in their Macao colony during the early sixteenth century, the Dutch established the Dutch East India Company during the same period and were the first to import tea to Europe. It was the British, however, who most took tea to heart, making it an integral part of their culture, trading it under the English East India Company out of Java, popularizing it globally, and mastering its cultivation.

The first public tea sale in Britain took place in the mid-1600s, beginning a commerce that would increase in volume to several million pounds annually by the late 1700s. The suspicious, protective (and perhaps wise) Chinese successfully denied information about the cultivation of tea to the British for so long that they did not fully understand that green, black, and oolong teas came from the same bush until the late nineteenth century. Tea plants were eventually discovered in Assam (between Burma and India) in the early nineteenth century, enabling the British to circumvent the Chinese and establish tea cultivation in India shortly thereafter, and in Ceylon during the later nineteenth century.

Tea services developed by the British were known as high tea or low tea and were common throughout their empire by the late seventeenth century. Low tea was served during the afternoon, usually around four o’clock, with sweets and bite-size sandwiches. High tea was served as an early dinner with a hot entrée and other tidbits. A tradition among the aristocracy, English teas are rather complex and precise rituals, employing a tea strainer (to hold back the brewed leaves) while pouring the infusion into the cup. Tea service was popularized in Hong Kong during its British colonization, and one of the best remaining examples of formal British tea service can still be experienced at the Peninsula Hotel, located in Kowloon, Hong Kong.

### Tea in India

Some Indian scholars argue that, like Buddhism, tea originated in India. This is often connected with the idea that wild tea plants were discovered in ancient Assam and then transplanted to China. While this is possible, the first records of the Indian aristocracy drinking tea date back only to the seventeenth century. Tea cultivation flourished in India under the British, however, and today India is the largest exporter of tea in the world.

This 1851 painting by Russian artist A. Voloskov shows a family gathered around a tea table for an elaborate afternoon repast.  
© ARCHIVO ICONOGRAFICO, S. A./CORBIS.

Darjeeling tea, for example, is grown in the foothills of the Himalayas, and is a prized Indian black tea. The use of milk and sugar in tea is also linked to India: while the Chinese and Japanese believe that the only way to drink tea is pure—without milk and sugar—Indians drink theirs with both. This convention may have originated with the British, who enjoy tea “light and sweet” to this day. It is also possible, however, that the Indians, who had enjoyed the milk of their sacred cows as a favorite beverage, developed it on their own and passed it on to the British.

### Tea in North America

Tea has frequently been associated with political turmoil historically. One well-known event has been credited with precipitating the American Revolution. The mid-eighteenth century was a time of both illegal Dutch tea smuggling and economic exploitation of the tea trade by the British in their North American colonies. The noto-

rious Tea Act of 1773 epitomized British manipulation of the tea market and pointed the way to possible future British abuse of American colonial tax law. Protests erupted in New York, Charleston, South Carolina, and, most famously, in Boston, Massachusetts, culminating in the Boston Tea Party of December 1773. Boston merchants marched to Griffin’s Wharf disguised in Mohawk headdresses, smashing and dumping tea chests from British East India boats into the water as an act of political defiance, instigating broader rebellion and, eventually, the American Revolution (1775–1782), which secured the independence of America from the British Empire.

Americans were able to plant and cultivate their own tea in the South, with particularly large plantations in South Carolina. It is said that tea, as part of that state’s overall agricultural wealth, allowed South Carolina to finance the Confederacy substantially during the American Civil War. The Charleston Tea Plantation in South

Carolina was established in 1799, eventually growing teas crops that originated in China, India, and Ceylon. It remains the only tea plantation in America today, producing an excellent orange pekoe black tea under the label American Classic Tea.

### Varieties of Tea

Tea can be broadly divided into three common types: green (unfermented), oolong (semi-fermented), and black (fermented). These are usually sold as loose whole leaves, pearled, crushed, powdered, cakes (preferred by Tibetans), and—beginning in modern times—the twentieth century, as individual tea bags. The Chinese prefer the green varieties for their unique and delicate floral notes. Understood to be the healthiest of all teas, fresh green tea is sometimes recommended as a modern cancer preventative and curative, primarily because of its high concentrations of antioxidants. The best of the green teas are considered to be those produced in the province of Szechuan, including a highly regarded, fragrant, and semisweet type variety called “Dragon’s Well.” The fresh varieties require a bit of fussing in their preparation and, for this reason, are usually reserved for both formal and informal social rituals as a result. Fermented teas were developed as a means of preservation, especially preservation related to early international trade and shipping, when long sea voyages would have caused the leaves to rot. Accordingly, black teas have enjoyed greater historical popularity in the West, where they were the prevalent type most readily available.

The price of tea—essentially its value—is determined by the quality and rarity of the leaf. As such a pound of tea can range from roughly ten dollars to one thousand dollars, with the best most expensive teas usually being those in the green tea category. Today’s quality teas come from China (Gunpowder, Pu’erh, Lapsang Souchong, Dragon’s Well), Taiwan (Imperial Oolong, Formosa White Tip, Jasmine), Japan (Sencha, Bencha, Matcha, Genmaicha), India (Assam, Darjeeling), and Sri Lanka (Ceylon). The word “blend” is used to describe teas composed of various tea leaves from different locales. Good examples of blended teas include English and Irish Breakfast teas. Scented teas are perfumed with ingredients such as oil of bergamot, magnolia, cassis, and other fruits or herbs. Examples of classic scented teas include Earl Grey and Jasmine tea.

### Tea as a Cooking Ingredient

Tea is also used as a cooking ingredient, imparting a bitter, sweet fragrance to dishes. Classic Chinese recipes include tea-boiled eggs, Hunan tea-smoked duck, and shrimp cooked with tea leaves—a specialty of the Imperial Court of Beijing. In Southeast Asia, especially Burma, pickled tea leaves—steamed, pressed into bamboo culms, and then buried until the tea is properly aged—are a popular snack, these having been steamed and pressed into bamboo culms, which are then buried until the tea is properly aged.

### Tea in the Contemporary World

Tea has spread throughout the world, becoming an important part of Southwest Asian, Central Asian, African, European, North and South American, and Australian culinary cultures. International tea drinking has been affected by invention and innovation. Ice (or “iced”) tea was invented early in the twentieth century, introduced by an Englishman, Richard Blechynden, at the 1904 World’s Fair, Louisiana Purchase Exposition, in St. Louis, Missouri, and helped to sustain the beverage’s popularity. Since then, ice tea is offered in private homes, public events, diners, fast-food chains, and restaurants the world over.

Tea bags were invented by Thomas Sullivan in 1908, which made it convenient to brew single servings of tea in individual cups quickly and simply. (It also kept the leaves from spreading into the drink, at once solving a problem and stripping the beverage of some of its ritual.) Tea bags rapidly became the most popular form of making tea. Fruit-flavored, sweetened teas have become increasingly popular, too, not only as stimulants but satisfying the American (and increasingly international) taste for sweet drinks. Powdered, “instant” ice teas also exist, a cultural counterpoint to periodic revivals of more complex teas such as Indian milk-based chais.

## TEA (MEAL)

The year 1840 is a landmark in culinary history. Antoine's restaurant had its beginnings in New Orleans, San Francisco consumed the first vintage of commercially produced California wine, and London society imitated Anna, the seventh Duchess of Bedford (1788–1861), with her cure for what she described as “a sinking feeling” she suffered each afternoon. It was then customary in England for the aristocracy to eat a huge breakfast, make do with a small lunch, and sit down to a substantial meal for dinner at eight o'clock or after. Milady's late afternoon discomfort was shared by many another and so was her cure: She ordered tea and a collation of sandwiches and cakes to complement the tea to be served daily at the stroke of five and invited friends to join her.

From the 1840s on, the tradition of afternoon tea with sandwiches and pastries trickled down from the aristocracy to enter English life at large. By the year of Anna's death, the conservative Mrs. Beeton's authoritative *Household Management* pronounced afternoon tea—“a meal of elegant trifles”—to be obligatory in any well-run Victorian household. Not long after Anna's death, the novelist George Gissing was to write, as if in tribute to her, “Nowhere is the English genius for domesticity more notably evidenced than in the festival of afternoon tea.” As it began, so it remained essentially a female ritual, but gradually two distinct “teas” evolved.

Aristocratic homes served what was called “low tea” in the afternoon. This was a repast of “elegant trifles” like cucumber sandwiches and other finger foods rather than solid nutrition; the emphasis was placed upon presentation of the foods and socializing over the delicacies. This “terribly, terribly nice” affair became known as “low tea” in contrast to the petty bourgeois and working class custom of “high tea,” which has also been called “meat tea” or “farmhouse tea.” These are family affairs—hearty, lavish spreads to satisfy the appetites of workers home from toiling and children hungry after school. High tea serves the humbler classes in Britain as the evening meal and often consists of such left-overs as cold joints of mutton, with fresh baked scones, buns, or biscuits and tea in abundance to warm the belly and banish fatigue. “High tea” is not parallel to “high church”; the more elegant

and ceremonious the tea, the further it departs from high tea. In Britain during Victoria's later years, teatime migrated from five o'clock to four, and its ceremonial aspects attained the very height of ostentation. Besides the evidence of Oscar Wilde's play *The Importance of Being Earnest* and Saki's short story “Tea,” we have historical accounts of these excesses. Margot Asquith, second wife of the British Liberal prime minister Lord Herbert Asquith (1852–1928), writes in her autobiography how the Rothschild family kept great state in, among other places, their home in Waddesdon, where one day Prime Minister Asquith was waited on at teatime by the butler. “Tea, coffee, or a peach from the wall, sir?” “Tea, please.” “China, Indian or Ceylon, sir?” “China, please.” “Lemon, milk, or cream, sir?” “Milk, please.” “Jersey, Holstein, or Shorthorn, sir?” Volumes could be written.

**THANKSGIVING.** The classic representation of Thanksgiving—a crowded dinner table set in the open air on a golden autumnal afternoon in Plymouth Colony, 1621—might include some anachronisms such as apples, potatoes, corn-on-the-cob, and cranberry sauce, but the gathered Pilgrims and their Wampanoag Indian guests are sure to have one of the “great store of wild turkeys” if not the geese, ducks, and venison that founded the historic feast, bowls of assorted root vegetables, and pumpkin pies. It is an idyllic scene, but it has nothing to do with how the Thanksgiving holiday historically began in America.

There never was a true “first” American Thanksgiving from which all subsequent celebrations derived. Thanksgiving did not originate in America at all, but arrived with the intellectual baggage of New England's Puritan colonists. Having banished the medieval roster of holidays including Christmas and saint's days, the reformers admitted only three holy days: the Sabbath, fast days, and Thanksgivings. Fasts and Thanksgivings sub-

sequently appeared independently in each of the New England colonies (except Rhode Island). Each was like an extra Sabbath during the week, requiring church attendance and sober activity, but a big dinner following the meeting was customary on days of thanksgiving and praise. Eventually, fast days were relegated to the spring (when there was nothing to eat) to petition God for a successful season, while autumnal Thanksgivings celebrated the cumulative blessings of the year, including the fruits of the harvest.

As Puritans metamorphosed into Yankees, the social and gustatory character of the day overtook and then equaled the religious observation in consequence. The preparation for the feast began weeks before with Sunday readings of the governor's proclamation. Apples, spices, suet and lean beef were chopped for mincemeat. Massive numbers of pies and tarts were baked of mince, pumpkin, apple, cranberry, and other fillings, intended to last well beyond the holiday. Livestock and fowl were slaughtered and prepared for the spit, pot, or chicken pie (which might take six birds, bones and all). The requisite turkey was gotten from the barnyard, market, or turkey shoot where poor shots underwrote the costs of better marksmen. Charity was an important holiday element. Food supplies, unprepared (including flour, rice, sugar, and even turkeys) or cooked, were given to the poor by prosperous families and sent to prisons by town officials.

As Thanksgiving approached, family and friends assembled at the patriarchal homesteads. Thanksgiving balls were very popular, and women made sure that their clothes were the best and newest possible, despite grumbling about impious frivolity among the more devout. On the day itself, the more respectable attended morning service in the meetinghouse, before returning for the customary feast prepared by the women and servants of the household. The signifiers of a true New England Thanksgiving dinner were firmly established by the time of the American Revolution: the all-important turkey in place of honor, the massive chicken pie flanked by ducks, geese, and cuts of "butcher's meat," plum pudding, bowls of vegetable and fruit "sass" (sauce), and of course the pies. Following the dinner, the company might relax around the fire with wine or cider, dried fruits, and nuts to play games, tell stories, or in more pious households, to continue their religious exercises in the private sphere and welcome the minister's evening call. Alternately, sleighing visits to other households were popular, as were dances and weddings.

Even before 1800, many households got their holiday foodstuffs not from the family farmstead but in the marketplace. The food was processed, prepared, and served by the housewife to as many family, friends, and dependents as could be accommodated. Later, the emphasis shifted to kin rather than community, but the classic Thanksgiving bill of fare, based on what was available in November in colonial New England, remained sacro-

Thanksgiving dinner is one of the most important occasions for American families of all faiths and ethnic backgrounds to come together and enjoy a large home-cooked meal. © STEVE CHENN/CORBIS.

sanct. Over the years the ideal of a home-prepared meal and informal family gathering has sent generations of women seeking the advice of experts from Catherine Beecher to Martha Stewart. Regional and ethnic variations were allowed, but the iconic turkey, cranberry sauce, and pumpkin (or squash) pie consecrated all true Thanksgiving meals.

The first of ten national Thanksgivings was declared by the Continental Congress in 1777. After 1815, there were no further presidential proclamations despite annual editorial pleadings by Mrs. Hale in *Godey's Magazine*, but the popularity of the holiday grew apace. By the 1850s, Thanksgiving was celebrated in almost every state and territory, its national character assured. Abraham Lincoln declared two Thanksgivings in 1863, the second in November being the first of our modern national holidays, but it was not until 1941 after Roosevelt fiddled with the date with an eye to Christmas sales that Congress established the fourth Thursday as a legal holiday. Aside from packaged versions of traditional foods, expenses associated with holiday travel, and a moderate amount of decorative kitsch, the holiday also escaped the exploitive commercialism of other American holidays. Restaurants take advantage of the holiday to sell turkey dinners, and those dedicated purveyors of classic Thanksgiving fare, the armed services, do their best, but Thanksgiving retains its strongly domestic focus.

In light of their modern importance as the symbols of the holiday, it might be asked. "What about the Pilgrims?" The fact is that the famous description of the 1621 harvest festival in Mourt's Relation had been entirely forgotten before being rediscovered in 1822 and identified as the "First Thanksgiving" by Alexander Young in 1841.

No one had associated the Plymouth colonists and Indian guests with the holiday before. However, in 1841 the event resembled contemporary Thanksgivings, even if it had not been so regarded by the original participants. The concept took time to catch on, as the Pilgrims had other symbolic burdens to bear, and Thanksgiving still implied family reunions, turkeys, and Yankee homesteads to most people. It wasn't until a fictional account appeared in the bestselling *Standish of Standish* (1889) that the Plymouth association gained widespread popularity, and only after World War II did the Pilgrims become the primary signifiers of the holiday.

**THIAMINE.** *See* **Vitamins.**

**THIRST.** Thirst is a conscious sensation that results in a desire to drink. Although all normal humans experience thirst, science can offer no precise definition of this phenomenon because it involves numerous physiological responses to a change in internal fluid status, complex patterns of central nervous system function, and

psychological motivation. Three factors are typically recognized as components of thirst: a body water deficit, brain integration of central and peripheral nerve messages relating to the need for water, and an urge to drink. In laboratory experiments, thirst is measured empirically with subjective perceptual scales (for example, ranging from "not thirsty at all" to "very, very thirsty") and drinking behavior is quantified by observing the timing and volume of fluid consumed.

Psychologists classify thirst as a drive, a basic compelling urge that motivates action. Other human drives involve a lack of nutrients (for example, glucose, sodium), oxygen, or sleep; these are satiated by eating, breathing, and sleeping. Clark Hull published a major, relevant theory describing the nature of human drives in 1943. He observed that learned habits, in addition to the thirst drive, influence drinking strongly. If a behavior reduces thirst, that behavior is reinforced and learned as a habit. Irrelevant behaviors (for example, sneezing, grooming) provide no reinforcement, have no effect on drinking, and do not become habits. Further, Hull realized that external incentives, such as the qualities or quantity of a fluid, also influence fluid consumption. On a hot summer day, for example, a cold beverage is more attractive than a cup of hot tea. Yet when chilled to a very low temperature, a cold beverage becomes an aversive stimulus to drinking behavior. Physiologists have popularized the term *alliesthesia* (from Greek root words referring to altered sensation) to describe the fact that the sensation of thirst may have either pleasant or unpleasant qualities, depending on the intensity of the stimulus and the state of the person.

Numerous investigations have verified that thirst and drinking behavior are complex entities. For example, drinking behavior (that is, the timing and the amount of fluid consumed) is not linearly related to the intensity of perceived thirst. Nor should we infer that individuals experience thirst simply because they drink. These facts indicate that thirst and drinking behavior are distinct entities that influence each other and are influenced by numerous internal and external factors.

#### Physiological Components of Thirst

Thirst is often viewed by physiologists and physicians as a central nervous system mechanism that regulates the body's water and minerals. The significance of the thirst drive is emphasized by three facts: 50 to 70 percent of adult body weight is water, the average adult ingests and loses 2.5 liters of water each day, and body weight is regulated within 0.2 percent from one day to the next. Clearly, water is essential to life and the body responds in a manner that ensures survival.

In 1954, Edward Adolph and colleagues proposed a multiple-factor theory of thirst that has not been refuted to date. This theory states that no single mechanism can account for all drinking behavior and that multiple mechanisms, sometimes with identical functions, act concur-

rently. Because water is essential to life, the existence of redundant mechanisms has great survival value. Among these, thirst appears to be regulated primarily by evaluation of changes in the concentration of extracellular fluid, measured as the osmolality of blood plasma. (Osmolality is a measurement that describes the concentration of all dissolved solids in a solution, that is, dissolved substances per unit of solvent. In research and clinical laboratories, the unit for osmolality of blood is mOsm/kg or milliosmoles per kilogram of water.)

Below a certain threshold level of plasma osmolality, thirst is absent. Above this threshold, a strong desire to drink appears in response to an increase of 2 to 3 percent in the level of dissolved substances in blood. The brain's thirst center lies deep within the brain, in an area known as the hypothalamus. This anatomical site contains cells that respond to changes in the concentration of body fluids. When the thirst center is stimulated by an increased concentration of blood (that is, dehydration), thirst and fluid consumption increase.

As the brain senses the concentration of blood, it allows a minor loss of body water before stimulating the drive to drink. This phenomenon has been named voluntary dehydration. Specifically, several research studies since the 1930s have observed that adults and children replace only 34 to 87 percent of the water lost as sweat, by drinking during exercise or labor in hot environments. The resulting dehydration is due to the fact that thirst is not perceived until a 1 to 2 percent body weight loss occurs. Interindividual differences, resulting in great voluntary dehydration in some individuals, have caused them to be named reluctant drinkers.

Reduced extracellular fluid volume, including blood volume, also increases thirst. Experiments (for example, reducing blood volume without altering blood concentration) have demonstrated that volume-sensitive receptors in the heart and blood vessels likely regulate drinking behavior by increasing the secretion of hormones. This effect is relatively minor, however. Animal research suggests that a change in extracellular fluid concentration accounts for most (for example, 70 percent) of the increased fluid consumption that follows moderate whole-body dehydration, whereas a decrease of fluid volume per se plays a secondary role.

Thus, thirst is extinguished when body fluid concentration decreases and fluid volume increases. Osmolality-sensitive nerves in the mouth, throat, and stomach also play a role in abating thirst. As fluid passes through the mouth and upper gastrointestinal tract, the sense of dryness decreases. When this fluid fills the stomach, stretch receptors sense an increase in gastric fullness and the thirst drive diminishes.

As dehydration causes the body's extracellular fluid to become more concentrated, the fluid inside cells moves outward, resulting in intracellular dehydration and cell shrinkage, and the hormone arginine vasopressin (AVP,

Down through the centuries, potters, glassblowers, and metal-smiths have devised clever and decorative ways to quench thirst. These Roman glass tumblers, discovered at Pompeii, were made by blowing the glass into wooden molds in order to create the raised patterns. Raised patterns helped the drinker hold the glass more firmly, thus lessening the likelihood of having it slip through the fingers when tipsy on wine. © MIMMO JODICE/CORBIS.

also known as the antidiuretic hormone) is released from the brain. AVP serves two purposes: to reduce urine output at the kidneys and to enhance thirst; both serve to restore normal fluid balance. Other hormones influence fluid-mineral balance directly and thirst indirectly. Renin, angiotensin II, and aldosterone are noteworthy examples. As dehydration reduces circulating blood volume, blood pressure decreases and renin is secreted from blood vessels inside the kidneys. Renin activates the hormone angiotensin II, which subsequently stimulates the release of aldosterone from the adrenal glands. Both angiotensin II and aldosterone increase blood pressure and enhance the retention of sodium and water; these effects indirectly reduce the intensity of thirst. Angiotensin II also affects thirst directly. When injected into sensitive areas of the brain, it causes a rapid increase in water consumption that is followed by a slower increase in sodium chloride consumption and water retention by the kidneys.

### Host Factors

Repeated training sessions in cool or hot environments alter fluid consumption in four ways. First, physical training increases the secretion of the hormone AVP, which stimulates drinking and body water retention. Second, exercise-heat acclimation (that is, adaptations due to exercise in a hot environment over eight days) increases the volume of fluid consumed and the number of times that adults drink during exercise. Third, frequent rest periods, in the midst of labor or exercise, will increase fluid replacement time and enhance fluid consumption.

## FACTORS THAT ALTER THIRST

### Increase Thirst

- increased concentration of blood
- decreased blood volume
- decreased blood pressure
- mouth and throat dryness
- increased angiotensin II

### Decrease Thirst

- decreased concentration of blood
- increased blood volume
- increased blood pressure
- increased stomach fullness
- decreased angiotensin II

Humans tend to drink less when they are preoccupied or are performing physical or mental tasks. Fourth, learned behaviors can enhance fluid consumption when thirst is absent. This phenomenon is widely appreciated among military personnel and athletes who are trained to consume water at regular intervals, whether they are thirsty or not.

Several research groups have reported that chronological age influences thirst and drinking behavior. Elderly men experience a blunted thirst drive and reduced fluid intake, perhaps due to their brains' reduced ability to sense changes in plasma osmolality or blood volume. Further, elderly individuals experience a decrease in the ability of their kidneys to conserve water. This suggests that the elderly are predisposed to dehydration when illness increases water loss (that is, vomiting, diarrhea) or when physical incapacity prevents access to water.

### Fluid and Environmental Characteristics

Many fluid characteristics stimulate or enhance drinking, during or after exposure to a hot environment. Fluid temperature (consumption is greatest at 14 to 16°C, reduced above 37°C), turbidity, sweetness, fruit flavorings (for example, cherry, grape, orange, lemon), addition of citric acid which imparts a citrus flavor, and addition of sodium chloride or other minerals are examples. These components enhance palatability and increase fluid consumption. The addition of a small amount of salt (sodium chloride), besides enhancing palatability, may result in thirst and increased drinking, due to the specific action of sodium on fluid movements. An increased sodium concentration outside of cells causes water to leave cells via osmosis. The resulting cellular dehydration is an important stimulus for drinking. Increased beverage carbonation tends to reduce the palatability of a fluid as well as the volume of fluid consumed, without an increase in thirst. In addition, intakes of food and water are closely related. During 24-hour observations of fluid intake, most studies report that the majority of fluid (69 to 78 percent) is consumed during meals. The foregoing characteristics, therefore, tend to reduce the magnitude of voluntary dehydration.

Conversely, fluid characteristics may influence drinking behavior negatively, regardless of the intensity of thirst. Experiments conducted during mild prolonged exercise have shown that the following qualities are perceived as undesirable: nausea, bloating, an objectionable feeling in the mouth, excessive viscosity, and excessive sweetness (see Passe, 1996). Exercise and high ambient temperature may independently alter an individual's perception of fluid palatability. For example, drinking behavior increases when air temperature exceeds 25°C. Fluid consumption can also be enhanced by changing the shape of a fluid container, proximity of fluid containers to the drinker, volume of fluid that is available, and time allowed for drinking.

Societal customs may influence fluid consumption, as evidenced by cross-cultural differences in beverage preferences. Even rituals, such as accepting the friendly offer of a beverage in a social setting, may enhance fluid intake beyond that driven by physiological cues. These factors usually involve learned habits. Similarly, when people repeatedly drink fluids with initially unfamiliar flavors, the palatability of the fluids is enhanced.

Although a comprehensive theory of thirst and fluid balance eludes description, it is likely that the thirst drive increases and diminishes because multiple factors (for example, oral dryness, gastric distension, osmolality, volume, fluid qualities) are integrated concurrently by the brain's thirst center.

**TILLAGE.** Farmers perform tillage when they prepare soil for the raising of crops. Soil tillage has three primary purposes. Prior to planting, farmers use tillage to mix compost, manure, and other fertilizers into the root zone where growing plant roots may reach it. Tillage also aids seed germination by creating a smooth, uniform soil surface for planting. After planting, farmers use tillage to control weeds between crop plants—including vegetable, fruit, forest, medicinal, and farm crops. Since early agriculture, tillage has been the first step in the process that makes it possible to harvest food from plants. However, soil tillage has come under close scrutiny since soil is recognized as a natural resource that deserves pro-

tection. Agronomists (scientists who study crop production and soil management) are concerned because erosion (soil loss) from tillage is one of the most significant problems in agriculture. If left unchecked, soil erosion leads to loss of soil productivity, as well as off-site deposition of sediments and farm chemicals that pollute surface and groundwater.

### Early History of Tillage

Soil tillage had its beginnings ten to twelve millennia ago in the Near East, as early farmers used a digging stick to loosen the soil before planting seeds. The tool evolved from digging stick to spade to triangular blade, and was made of wood, stone, and ultimately metal. One or more people likely used their bodies to pull the first wooden plows. Animals began pulling plows around 3000 B.C.E. in Mesopotamia. Jethro Tull (1674–1741), a pioneering British soil physicist, was the first to recognize that loosening soil helps to supply plant roots with nutrients.

In North America, agricultural innovators copied European trends. Charles Newbold patented the first cast-iron plow in the late 1700s. In 1837, John Deere and Leonard Andrus began manufacturing steel plows. By the 1840s, the growing use of manufactured equipment had increased the farmers' need for cash, thus encouraging the rise of commercial farming. Agriculture, society, and economics were closely linked, as George Marsh said in an address delivered in 1847 to the Agricultural Society of Rutland County, Vermont: "Pure pastoral life, as I have said, advances man to but an humble stage of civilization, but when it is merged in agriculture, and the regular tillage of the soil commences, he is brought under the dominion of new influences, and the whole economy of domestic and social life is completely revolutionized." Marsh explained that once cultivation of soil begins, all aspects of society are affected by changes: "Hence arises the necessity of fixed habitations and store houses, and of laws which shall recognize and protect private exclusive right to determinate portions of the common earth, and sanction and regulate the right of inheritance, and the power of alienation and devise, in short the whole frame work of civil society."

Horses and mules had taken over the work of draft oxen by the late 1800s. As agriculture became increasingly mechanized and commercialized, tractors became more common and replaced most draft animals by the early to mid-1900s. Until then, the size of most family farms was restricted to the land that a man could work using several horses. With the advent of the light, gasoline-powered tractor, both family and commercial farms added crop area and prospered.

### The Dust Bowl

Tractors helped to create farm fields that stretched far westward, setting the stage for the Dust Bowl in the 1930s. Open grassland in the southwestern Great Plains region of the United States was settled and farmed by

Tilling with draught animals is a dying art, for both farmer and team must be well-trained to accomplish plowing in the quickest and most efficient manner. This elderly farmer is using a horse team in fields near Melk, Austria. © ADAM WOOLFITT/CORBIS.

homesteaders who planted row crops and grazed their cattle. Before farmers came, the region was covered by hardy grasses that held the soil in place despite long droughts and torrential rains. Tillage combined with drought left the soil exposed to wind erosion. Lightweight soil components—organic matter, clay, and silt—were carried great distances by the winds, while sand and heavier materials drifted against houses, fences, and barns. This drifting debris buried farm buildings and darkened the sky as far as the Atlantic coast. Over a period of ten years, millions of acres of farmland became useless, and hundreds of thousands of people were forced to leave their homes.

The Dust Bowl gave impetus to the soil conservation movement; nevertheless, mechanization continued to spread. In 1938, Hugh Bennett and Walter Lowdermilk of the United States Soil Conservation Service wrote in the *Yearbook of Agriculture*: “Soil erosion is as old as farming. It began when the first heavy rain struck the first furrow turned by a crude implement of tillage in the hands of prehistoric man. It has been going on ever since, wherever man’s culture of the earth has bared the soil to rain and wind.”

### Conservation Tillage and Sustainable Agriculture

By 1954, the number of tractors on farms exceeded the number of horses and mules for the first time. The increasing availability of agricultural chemicals in the mid-to late-1900s, including weed killers that did not harm crop plants, further changed crop and soil management practices. “Conservation tillage”—a broad spectrum of farming methods that help to reduce soil erosion due to wind and water and help to reduce labor and fuel—gained a following among farmers in the 1980s. Early methods of conservation tillage, such as no-tillage, were *unsustainable* since they relied heavily on chemical weed killers

called herbicides. The no-tillage method worked well to control both soil erosion and weeds, while requiring less energy. However, herbicides were highly toxic to people and wildlife and their manufacture and use caused environmental pollution. Tillage reduction methods were fine-tuned to suit local conditions throughout the United States.

By 1989, a far-sighted handful of new-generation farmers became interested in lowering costs, avoiding agricultural chemicals, and saving soil. They started the agricultural movement that became known as “sustainable agriculture.” Low-input methods meet the needs of more farmers each year. They are promoted by a program of the United States Department of Agriculture called Sustainable Agriculture Research and Education (SARE). Farmers practicing sustainable agriculture produce food and fiber while enhancing environmental quality and natural resources, make the most efficient use of nonrenewable resources and on-farm resources. Further, they integrate natural biological cycles and pest controls and sustain the economic viability of farm operations.

Today’s tillage practices reflect society’s concern with environmental quality, and the farmer’s need to reduce costs while preventing soil erosion and compaction. However, significant amounts of soil are still lost annually around the world where soil is not protected.

**TIME.** “Time” may not spring to mind immediately when one thinks of food, but time is always a factor. After all, recipes generally incorporate an element of time (for example, “let rise for four hours” or “bake for forty-

five minutes”), cooking preparation involves time, and various demands drive the length of meals. Thus, time has an impact on one’s daily food and food-preparation routine, and this impact is a particularly gendered process.

In nearly all parts of the world, cooking is a female task (Murdock and Provost, 1973). Women’s time is bounded by food-preparation tasks, particularly if they must perform those tasks several times a day (for example, tasks such as tortilla preparation, millet pounding, and the preparation from scratch of several meals a day). Alteration of a daily routine, for example, the intrusion of a more “urban” or fast-paced schedule, can alter food-preparation patterns. If women enter a market economy, they have less time to prepare food, which leads to, among other things, increased purchases of prepared food and more business for the fast-food industry. Time and food preparation are also markers of rank or class, since elaborate meals are generally costly in terms of time preparation as well as ingredients—in most societies, only the well-to-do, who have either time or help or both, can prepare elaborate meals. These widespread changes in food-preparation patterns are part of urban Western culture, where convenience and fast-food items (the names of which indicate their purpose) are replacing daily meal preparation. The Italian “slow food” movement is counterpoised against this trend.

### Food Preparation

The preparation of foods—the transformation from a raw or unprocessed state to one suitable for consumption—occupies a major portion of many women’s time throughout much of the world. For rural women and those in developing nations, preparation of meals may take up the major portion of a woman’s waking life. Since staple foods must undergo a lengthy preparation process, women can spend much of their time processing grain, nuts, or tubers, in addition to meal preparation itself. (This pattern has antecedents in the West, as well: consider the time needed to make bread and churn butter.)

Accompanying this ongoing preparation of staples is the routine of meal preparation. For example, Andean Ecuador meal preparation, which is performed from scratch twice a day, generally involves two to three hours of potato peeling, water boiling, and construction of the soup that constitutes the staple meal (Weismantel, 1988). In southern Mexico, rural Maya women may prepare up to two hundred tortillas per day, grinding and cooking them at each of two or three meals (Eber, 2000). In rural Africa, women farmers grind the standard grains, usually millet or sorghum, into flour for porridge or soup on a daily basis. Pounding millet, as this process is called, occurs at least once a day, and sometimes more often as needs demand. African women are also responsible for preparing and assembling meals. In Western urban settings, the food-preparation process may be slightly less rigorous, but often remains time-consuming, since the cook must peel, chop, and cook.

### Scheduling and Meals

The timing of meals is culturally determined and is linked to preindustrial work patterns, particularly the agricultural cycle. Throughout Latin America, the main meal of the day traditionally falls in mid-afternoon. The siesta, stereotypically seen by North Americans as a sign of indolence, is actually the main meal of the day. This pattern remains intact in smaller cities and rural areas, though the demands of global business are increasingly pushing urban workers into the short noon lunch typical of the United States. Among rural indigenous peoples, however, mealtimes may differ, following much more closely the requirements of subsistence farming. Breakfast is eaten very early in the morning, and a second, larger meal follows in the late morning or early afternoon. Another meal occurs in early evening, with an occasional snack before bedtime (which also occurs early, often shortly after sundown). At the same time, much of the urban world has already adopted a meal schedule that better conforms to the demands of industrialism. Such changes may alter or eliminate traditional meals or reduce the time families spend together (Rotenberg, 1992).

### Food, Time, and Class

Social standing shapes the ways in which food and time intersect. For those with sufficient income, only one member of a family need work, leaving the other family members at home to prepare traditional meals. Another alternative to preparing food for oneself is to hire a professional cook, who is also able to prepare meals from scratch.

For those with little money and little time, the options decrease. Convenience and fast-foods are expensive for what they provide, and they are often limited to single or perhaps two servings. Time, money, and class intersect in other ways that affect meals, as well. For the working poor, hours of overtime, or even two jobs, may take up the time that would otherwise be spent preparing and eating meals; meager wages may also reduce one’s housing choices. In her book on the working poor, *Nickel and Dime*d, Barbara Ehrenreich describes this housing process: Unable to afford housing with a kitchen, the worker cannot purchase foods to prepare in bulk and cannot store or freeze these foods. Such workers are sometimes entirely dependent on meals they can purchase and eat immediately, such as fast-food or the kinds of overpriced but affordable snack food sold in convenience stores.

### Changing Time and Changing Food

The impact of urban work patterns has affected mealtimes, food choices, and diet throughout the world. As workers move from an agrarian life to one driven by waged work, they shape their mealtimes to that of the workplace rather than the farm. The kinds of foods workers choose to eat are likely to be those that can be taken to the workplace or eaten on the run. The rise in sales

of prepared foods appears to inevitably accompany women's entry into the workforce, and sometimes women themselves enter the workforce to provide the prepared food, a pattern seen in Peru (Babb, 1998), rural Africa (Clark, 1994), and elsewhere. The ability to bring home prepared food enables women to spend longer periods of time working in a pattern that parallels western women's purchase of fast-food dinners for the family. For the westerner and the rural worker alike, elaborate meals requiring lengthy preparation become increasingly associated with ritual and holiday feasting. The role of time in the preparation of holiday foods rather than (or in addition to) the use of special ingredients marks them as special treats. This stands in contrast to the faster and less elaborate meals consumed during a regular workweek. Sidney Mintz, in his work *Sweetness and Power*, has further suggested that the increasing consumption of sugar in tea allowed the shift of displaced rural English into industrial labor—they could consume cheap quick meals of tea and bread and spend much of their time working.

The speedy meal is familiar also in the form of the fast-food industry that the demands of postindustrial capitalism shaped. The busy worker can order, pick up, and pay for a quick and generally tasty meal, all without ever leaving the car. Eric Schlosser has described in-depth the quite extensive impact of the fast-food industry on diet, food production, and meal patterns in his book *Fast Food Nation*. While answering the demand for quick, easily consumed meals, the fast-food industry has also shaped marketing, taste preferences, and even agricultural practice.

The "slow food" movement has arisen in opposition to the pervasiveness of the fast-food industry. Founded in Italy, "slow food" promotes local and organic foods, family mealtimes, and the role of food in social life. In general, this movement opposes the increasingly mechanized and driven work life that the fast-food industry and North American culture represent (Inouye, 2001).

**TOMATO.** The *Lycopersicon* genus of the Solanaceae family originated along the coastal highlands of western South America. The genus is composed of nine generally accepted species, of which only two are used for culinary purposes: *L. esculentum*, the common tomato, and, to a much smaller extent, *L. pimpinellifolium*. Ripe, raw tomatoes consist of approximately 93 percent water. Consuming one hundred grams of raw tomatoes provides seventeen grams of carbohydrates, three grams of protein, twenty-three grams of vitamin C, or about forty percent of the adult recommended daily allowance (RDA), and about nine hundred international units of vitamin A, or about 30 percent of the adult RDA. Today, the tomato is one of the most commonly eaten foods in the world with almost every cuisine employing them in some form.

In the United States, tomatoes are second only to potatoes in U.S. vegetable consumption. During the 1980s and 1990s, U.S. annual per capita use of tomatoes and tomato products has increased by nearly 30 percent, reaching an annual total fresh-weight equivalent of 91 pounds per person by 1999. By that date, the total world production was 111.1 million short tons. Until recently, the United States was the world's largest tomato producer. However, during 1999 China was ranked the largest tomato producer with 18 million short tons, followed by the United States (12.7 million short tons), Turkey, Egypt, and Italy.

#### The Spread of the Tomato

Although the tomato originated in South America, little evidence has surfaced indicating that indigenous peoples in South America ate tomatoes before the Spanish conquest in the sixteenth century. In pre-Columbian times the tomato migrated by unknown means to Central America, where it was domesticated by Mesoamerican peoples. When the Europeans arrived, tomatoes were consumed only in a narrow geographical area from Central America to Mexico City. This lack of widespread diffusion has led observers to conclude that tomatoes were a late addition to the culinary repertoire of Mesoamerica. The Spanish first encountered tomatoes after their conquest of Mexico began in 1519. Tomato plants were disseminated first to the Caribbean, and then to Spain

and Italy. From Central America, domesticated tomatoes were introduced into South America by the Spanish Conquistadors. Toward the end of the sixteenth century, tomatoes traveled west to the Philippines, from where they were introduced into Indonesia and later onto the Asian mainland.

Tomatoes were consumed in southern Italy and Spain by the mid-sixteenth century. The first published record of the tomato appeared in an 1544 Italian herbal. By the late seventeenth century, the first known tomato recipes appeared in the cookbook *Lo scalco alla moderna* (Naples, 1692), by Antonio Latini. By this time, tomatoes were also consumed in the eastern Mediterranean and North Africa. Tomato cookery took off in southern France late in the eighteenth century and tomato recipes appeared in French cookbooks by the early nineteenth century. Tomatoes were cultivated in England by 1597; however, little evidence for British consumption has been found prior to the mid-eighteenth century.

Beginning in the seventeenth century, Spanish colonists introduced tomatoes into their settlements in Florida, New Mexico, Texas, and California. As English settlers visited and occupied territories previously controlled or influenced by Spain and Mexico, they were exposed to tomato cookery. Some American colonists ate tomatoes as early as the mid-eighteenth century, although only one colonial cookery manuscript is known to have contained a tomato recipe. From the Southern states, tomato culture slowly spread up the Atlantic coast and into rural areas. By the early nineteenth century, tomato recipes frequently appeared in American cookery manuscripts and cookbooks. By the mid-nineteenth century, tomatoes were a common part of cookery throughout western Europe, the Mediterranean and the Americas. Tomato cookery later expanded into Northern and Eastern Europe, and finally spread to sub-Saharan Africa, and South and East Asia.

### Procurement

Traditionally, all aspects of tomato sowing, growing, and harvesting were accomplished by hand. Beginning in the late nineteenth century, machinery began to assist farmers in planting, sowing, and weeding. Although all fresh tomatoes continue to be picked by hand today, tomatoes used for processing are picked by mechanical harvesters, which were first successfully employed in California during the 1950s.

Beginning in the early nineteenth century, tomatoes were bottled by the Frenchman Nicholas Appert. In the United States, tomato canning and bottling began in New Jersey during the 1840s. It expanded during the Civil War, and by 1870 tomatoes were among the top three canned products in America. Tomato cultivation increased in northern states, such as Maryland, Delaware, Pennsylvania, and Ohio, and spread south and west after the war. Today, California grows the largest number of tomatoes, with about 80 percent of total U.S. production.

### THE FIRST KNOWN AMERICAN TOMATO RECIPE

To Keep Tomatoes for Winter use

Take ripe Tomatoes, peel them, and cut them in four and put them into a stew pan, strew over them a great quantity of Pepper and Salt; cover it up close and let it stand an Hour, then put it on the fire and let it stew quick till the liquor is intirely boild away; then take them up and put it into pint Potts, and when cold pour melted butter over them about an inch thick. They commonly take a whole day to stew. Each pot will make two Soups.

N.B. if you do them before the month of Oct they will not keep.

SOURCE: Harriott Pinckney Horry Papers, 28. The Collections of the South Carolina Historical Society.

### Tomato Canning

The major use of tomatoes is the canning of four major products: whole tomatoes, tomato sauce, tomato paste, and tomato soup. The first canneries processed whole tomatoes. These efforts began in the 1850s and were labor-intensive operations. The fruit were skinned, cored, and trimmed. Cans were fashioned by hand, and the seams were soldered on. These were then boiled in water. The cans were hand-filled, then given to the cappers, who soldered on the lids one at a time. A few days later the cans were hand labeled, loaded onto wagons, and carted to stores.

Before long, every stage of the canning operation had a machine associated with its operation. Devices for capping, filling, scalding, topping, and wiping were introduced, as were power hoists and cranes. Wrapping and boxing machines also soon came into use. Equipment manufacturers developed lines of interconnected equipment. New machinery was released about 1903, providing for the fully automated manufacture of sanitary cans. By the 1920s, the process of canning tomatoes was fully automated. From the time tomatoes arrived by truck until the canned goods were shipped out the back door, the tomatoes were never touched by human hands. Subsequent developments in machinery sped up the process and made it more efficient.

During the 1950s, evaporators originally developed for the dairy industry were adapted for use in tomato processing. The evaporators rapidly remove water and concentrate the pulp to forty-two percent solids. Some concentrate is frozen via flash coolers, which remove water and heat, as the paste falls through the machine. The chilled concentrate is then stored in drums and used when

## THE TOMATO: VEGETABLE OR FRUIT?

The edible portion of the tomato is botanically a fruit (defined as a ripened ovary!) as is the edible portion of melons, cucumbers, eggplants, and hot and sweet peppers. However, these plants are considered vegetables both horticulturally and in common English usage. A vegetable in the culinary sense is thought of as an edible herbaceous (soft-stemmed) plant of which some part is eaten, often in the main part of a meal; this includes the fruit as in tomato, the leaves in lettuce, the stem in asparagus, the root in beet, and the seed in the garden pea. The edible portions are also referred to as vegetables. Fruit plants in the horticultural sense are plants in which a more or less succulent fruit or closely related structure is eaten (but usually as a dessert or a snack). In this case the edible portion is also called a fruit, even if it is not clearly a fruit botanically. We call a strawberry a fruit, but it is the hard little seeds that are the botanical fruits (one-seeded fruits called achenes). Fruit plants are most often perennial and usually woody (exceptions include strawberry and banana, which are not truly woody). Fruit plants with fruits borne on trees are termed tree fruits, fruits borne on low-growing plants are called small fruits, and those on vines are called vine fruits. Nuts are a special subcategory of fruits characterized by having a hard shell separating the inner kernel of the seed. There is no precise distinction that can be made between the terms "fruit" and "vegetable." In the case of tomato, confusion can be avoided by referring to it as a "vegetable fruit." In 1893 the U.S. Supreme Court ruled that the tomato was legally a vegetable in a decision resolving a dispute concerning import duties, making an important legal point that the meanings of terms used in laws and statutes refer to common everyday meanings, not necessarily the scientific meanings.

*Jules Janick*

needed. Other concentrate is pumped into aseptic bags, which exclude outside air. Framed in collapsible wooden boxes, the bags are placed on trucks and shipped to factories for conversion into tomato products.

### Ketchup Production

Another major use of tomatoes in the United States is in the production of ketchup. Initially, ketchup production began as an attempt to use leftovers from the canning

process. These scraps were placed in barrels during the high canning season in September and October and were saved for later conversion into ketchup. As tomato ketchup became more popular, factories emerged that specialized solely in its production. Because the bright red color of the ketchup was an important selling point, ketchup was placed in bottles so that the consumer could see its color. Long narrow-nosed bottles with small holes were employed to reduce contact with air, which oxidized ketchup and turned it a deep dark color. Early ketchup bottlers had great difficulty preventing the introduction of air through the cap. In the early part of the twentieth century researchers developed improved glass bottles that would not shatter during the manufacturing process. Corks were covered with a metal cap that effectively sealed the bottle from contact with outside air. As capping technology improved, screw caps replaced corks.

Early ketchups were thin and were easy to pour out of the small hole at the top of the bottles. After the passage of the Pure Food and Drug Act in 1906, thick ketchup became the norm in order to meet the new federal standards. Thick ketchups were difficult to pour through the narrow spout, but consumers were already familiar with the narrow nosed bottle and commercial manufacturers had invested time, effort, and funds in creating an image for their bottle.

Packaging changes since the 1970s have greatly increased ketchup usage. The H. J. Heinz Company, the largest ketchup producer in the world, introduced the Vol-Pak, a plastic bag filled aseptically with ketchup. Designed for foodservice operators, restaurants placed the bag on a rack and refilled plastic bottles. The Vol-Pak soon replaced cans. During the 1980s, two additional packaging revolutions occurred: the single-serve ketchup pouch, for which production increased from half a million cases to five million cases in just ten years; and the squeezable plastic ketchup bottle, which was easier to use, and almost unbreakable. By the 1990s, sixty percent of all U.S. ketchup was sold in plastic containers.

### Preparation and Consumption

Tomatoes were employed by pre-Columbian Aztecs and other indigenous peoples of Central America for making sauces, particularly in combination with chili peppers and ground squash seeds. After the Spanish conquest, vinegar was added to the tomato and chili peppers to produce salsa. Numerous other uses for the tomato were developed in Mexico and Central America. In Europe, the first tomato recipe appeared in an 1544 Italian herbal, which recommended that tomatoes should be fried in olive oil and seasoned with salt and pepper. Variations of this recipe were published regularly in Europe and later in the Americas. Within a hundred years, tomatoes were well established in southern Italian cookery. The first tomato recipe appeared in a British cookbook in the late eighteenth century. The first known American tomato recipe appeared in Harriott Pinckney Horry's cookery manuscript, dated 1770.

Tomato recipes regularly appeared in American cookbooks by 1792. Early recipes fell into several major categories; the most important was tomato sauce, which originated in Italy and Spain and had migrated to southern France before 1800. Tomato sauce was used on beef, veal, fowl, chicken, rabbit, sweetmeats, pork, macaroni, fish, shrimp, and pigeon. Tomatoes were used to make marmalades, soups, gumbos, gazpacho, ketchups, sweetbreads, jumbles, dumplings, puddings, jelly, figs, omelets, and many other dishes. Tomatoes were stewed, baked, fried, stuffed, hashed, pickled, broiled, scalloped, forced, pickled, and preserved. Green tomatoes were consumed from the beginning, and sometimes were used for seasoning and gravy. Tomatoes were combined with many other vegetables to be consumed as side dishes, including okra and potatoes. Tomatoes were served raw at all meals. Raw tomatoes were seasoned with sugar, molasses, vinegar, salt, pepper, mustard, or milk. The most common way to eat raw tomatoes was sliced and seasoned, like cucumbers, with vinegar, salt, and pepper. Others plucked them from the vine and ate them like ripe fruit, without seasoning.

American restaurants were opened toward the end of the eighteenth century, mostly by French refugees. Their clientele consisted of businessmen and an increasingly affluent upper class. Tomatoes were served in these restaurants at least by the 1820s and probably much earlier. From their inception, restaurants offered a variety of tomato dishes. Tomatoes were noted on hotel menus by 1825. By the 1840s the diversity of tomato dishes dramatically increased.

Tomatoes were also employed to make beverages. The earliest beverages were alcoholic: beer, whisky, champagne, and wine, none of which were particularly successful. The drinking of tomato juice was a mid-twentieth-century phenomenon. According to several accounts, tomato juice was the creation of the American-born French Chef Louis Perrin, who in 1917 served tomato juice to his guests at a resort in French Lick Springs, Indiana. However, none of the early products yielded juice with just the right color and flavor. The reason for the failure of canned tomato juice was that tomato solids settled at the bottom of the can or in the glass when poured out. In 1928, this problem was solved by Ralph Kemp of Frankfort, Indiana, who used a viscolizer previously employed in the manufacture of ice cream. Tomato juice was an instant hit with the American public. Heinz and the Campbell Soup Company moved into high gear to produce tomato juice. One reason that tomato juice was so successful was the end of prohibition. A cocktail made of tomato juice and vodka was probably first developed at Harry's Bar in Paris by Ferdinand "Pete" Petiot, who moved to New York in 1933 and introduced his new creation. After experimentation, he added Worcestershire sauce and called it a Bloody Mary.

Another tomato product was V8 vegetable juice, a blend of eight vegetables along with several flavor-

The "Quarter Century Tomato" introduced in 1901 by Philadelphia seedsman William Henry Maule. During the fifty-year period from about 1875 to 1925, American seed companies vied with each other to develop newer and better tomatoes every year, owing to the popularity of tomatoes among home gardeners. enhancers. It had been conceived in 1933 by W. G. Peacock of Evanston, Illinois. Several people worked on the formula. Peacock interested three investors, and the New England Products Company was created. The product was first created in 1936 under the name "Veg-min" juice. At the first store that sold it, a clerk suggested that they change its name to "V-8," which Peacock did. Later the hyphen was removed and the product was marketed as V8 Cocktail Vegetable Juices. Peacock's entire operation was accomplished by hand, and he only had the ability to produce twenty-five cases per day. V8 juice was a success, but he did not have sufficient manufacturing capability to meet the demand. Peacock sold the V8 formula, and in 1948 the product ended up at the Campbell Soup Company, which is the largest tomato user in the world.

### Relation to Human Biology

While there are many reasons for identifying the tomato as a healthy vegetable, the specific attributes that have generated the latest interest are the carotenoids, a family

## LOVE APPLES

I gather love-apples very ripe, when they have acquired their beautiful colour. Having washed and drained them, I cut them into pieces, and dissolve them over the fire in a copper vessel well tinned. When they are well dissolved and reduced one third in compass, I strain them through a sieve sufficiently fine to hold the kernels. When the whole has passed through, I replace the decoction on the fire, and I condense it till there remains only one third of the first quantity. Then I let them become cool in stone pans, and put them in bottles, &c. in order to give them one, good boiling only, in the water-bath.

of pigments found in yellow, orange, and red vegetables and in green leafy vegetables. There are over six hundred carotenoids, but the predominant one in tomatoes is lycopene, a pigment that gives tomatoes their red color. The human body cannot manufacture Lycopene or other carotenoids. Some studies have offered evidence that foods rich in antioxidants and carotenoids may play a role in preventing certain types of cancer. Dr. Edward Giovannucci, an assistant professor in the Department of Nutrition at Harvard School of Public Health and the Department of Medicine at the Harvard Medical School, examined responses of fifty thousand participants in the Harvard University Professionals Health Study that began in 1986. He concluded that the consumption of four vegetables and fruits were associated with lower prostate cancer risk: three of the foods he cited were tomato sauce, tomatoes, and pizza. Lycopene is present in each of these. The risk of prostate cancer was one third lower in men who ate tomato-based products. In another study in northern Italy, a high correlation was drawn between tomato consumption and the lack of cancers of the digestive track. Of the 2,700 respondents, those who consumed seven or more servings of raw tomatoes every week had 60 percent less chance of developing cancer of the colon, rectum, and stomach.

Diets with abundant tomatoes cooked in oil were more readily absorbed than other forms of tomato. Pizzas and raw tomatoes were also protective against prostate cancer, but tomato juice was not. Giovannucci believed that cooking broke down the tomatoes' cell walls, releasing more lycopene, and that the oil enhanced absorption of the fat-soluble carotenoid. In the case of raw tomatoes, salad oil may have contributed in a similar manner.

## Symbolism

The tomato has become deeply entwined with popular culture throughout the world. In Japan a bank is named for it. In America tomato is slang for an attractive woman. Perhaps the most universal activity has been tomato throwing, a tradition that dates from the mid-nineteenth century. This tradition started in rural areas and moved to theaters to express lack of appreciation. Recently politicians have been the favorite target of tomato throwers. During the late 1940s, tomato throwing became an organized event in Bunyol, a town 25 miles west of the Mediterranean city of Valencia, Spain. The Tomatina festival, held on the last Wednesday in August, has been officially sponsored by the city since 1979. More than 30,000 people pelt each other and the city with tomatoes for a hour.

Other tomato festivals are held in other countries, including the United States. The Reynoldsburg Tomato Festival in Ohio attracts 35,000 residents who engage in tomato contests and consume tomato cookery. The Kendall-Jackson Heirloom Tomato Festival, held just north of Santa Rosa, California, featured tastings from more than 100 heirloom tomato varieties.

## Contemporary Issues

Beginning in the 1950s, botanists induced genetic mutations with X rays and chemicals. These mutants were mainly of interest to researchers. The research, however, encouraged further investigations into the chromosomal structure of the tomato, making more sophisticated alterations possible. During the late twentieth and early twenty-first centuries, this research began to be productive. In a project funded by Campbell's Soup Company, Calgene, Inc., in Davis, California, genetically engineered the first tomato, called MacGregor's, which was slow-ripening and transportable over great distances.

Calgene had conducted research concluding that the rapid softening of ripe tomatoes was caused by an enzyme called Polygalacturonase, or PG. Calgene spliced into the tomato's genes an extra one to cancel out the effect of the PG enzyme, and thus created the Flavr Savr. Thus, the tomato remained firmer in its last week and could be left on the vine to ripen for extra days. After a week or so of extra firmness, the Calgene tomato softens and decays like other tomatoes. The company voluntarily presented their genetically altered tomato to the U.S. Food and Drug Administration (FDA) for approval. The genetically engineered tomato was approved by the FDA's Food Advisory Committee. Since 1994, genetically altered tomatoes have been sold in grocery stores. Other genetically engineered tomatoes are under development. Other companies with strong biotech programs include DNA Plant Technology, Petroseed, Monsanto, Pioneer, and Dupont.

Many critics have strongly opposed genetic engineering of the tomato as presenting an unacceptable risk for humans. Some grocery stores have refused to sell ge-

netically engineered tomatoes, while others have agreed to identify them as genetically engineered. Restaurants have announced that they will boycott the new “mutant” tomatoes. A major concern is that there is no requirement that the genetically altered foods be labeled as such. Many critics believe they have the right to know which products have been altered and which are natural.

**TOURISM.** Food has always been a component of tourism. As a physical necessity and as a prominent arena for expressing creativity and for embodying cultural and individual identity, food has functioned as destination, venue, and vehicle for tourism. As destination, food is the primary experience sought. The preparation, consumption, and even the viewing of a foreign dish gives the tourist a sense of otherness and the exotic. As vehicle, food offers an entry point for viewing another culture. The sensory attributes of food enable consumers to feel a deeper level of experiencing; by ingesting food representing another culture, they can feel that they ingest that

culture. As venue, food offers a site from which a culture can be explored. These aspects can be commercial or domestic, public or private, festive or ordinary. Restaurants, festivals, cookbooks, grocery stores, private festive food events, cooking classes, cooking shows, advertising, literature, films, tourism brochures, food tours, and other such sites are physical loci for experiencing tourism. They also offer a tangible, knowable base from which other facets of culture—history, religion, artistic traditions, customs—can be understood and experienced.

Tourism is generally thought of as an activity in which individuals explore a culture that is foreign to them. Valene Smith defines a tourist as “a temporarily leisured person who voluntarily visits a place away from home for the purpose of experiencing a change” (*Hosts and Guests*, p. 1). The theme of tourism as spiritual and emotional quest appears frequently in scholarly works. Dean MacCannell sees tourism as a modern phenomenon in which tourists are on a quest to recover lost authenticity: it offers a way for modern man to explore the “real life” of others (*A New Theory of the Leisure Class*, p. 91). Mark Neumann suggests that “tourism is a metaphor for our struggle to make sense of our self and world within a highly differentiated culture” (“Wandering Through the Museum: Experience and Identity in a Spectator Culture,” p. 22). Most scholars of tourism now see tourism both as a state of mind in which anything, including the everyday and the local, can be subjected to the “tourist gaze”—to borrow John Urry’s book title—and as a continuum of types of experiences involving otherness. Erik Cohen offers a typology of tourists based on their concept and concern with authenticity: existential, experimental, experiential, recreational, and diversionary tourists (“Authenticity and Commoditization in Tourism”). Valene Smith, in *Going Places*, outlines a typology of tourists based on aspects of culture being explored and on the motivations of the tourist: ethnic, cultural, historical, environmental, recreational. Maxine Feifer adds the “post-tourist” who sees tourism as a game and inherently inauthentic in its experiencing of another culture.

Culinary tourism is a theoretical framework for analyzing the role of food in tourism. It refers to the “intentional, exploratory participation in the foodways of an Other.” It is voluntary and consciously contains an element of curiosity—that is, people eating out of choice, not only physical need.

The term “foodways” involves all the other aspects of food, referring to the network of activities and systems—physical, social, communicative, cultural, economic, spiritual, and aesthetic—surrounding the product itself: procurement, preparation, preservation, presentation, consumption, clean-up, and conceptualization. In this sense, culinary tourism can occur in any aspect of foodways, from purchasing familiar ingredients from a new grocery store to adding exotic ingredients to a familiar recipe. It can also include behaviors connected to

thinking and talking about food: collecting recipes, watching televised cooking shows or films incorporating food, conversing about restaurants, reading cookbooks and food columns, reminiscing about food experiences.

The culinary Other is simply anything different from the known and familiar. It can be broken into six overlapping categories. National or cultural identity is the most commonly perceived category and includes "ethnic" foods as well as "foreign" foods. Foods become a cultural Other by being placed in a context in which they are different. Thus, kimchi is standard fare in Korea, but is ethnic and foreign in the United States.

Region is the second category of Other and refers to groupings within a culture, differentiated by geographic location and physical resources. Within the United States, regional foods from areas such as the South (grits, fried chicken, hominy, corn bread), New England (baked beans, lobster, boiled suppers), the Southwest (chili peppers, Mexican-based foods), the Mid-Atlantic states (crab and seafood), and even the Midwest (meatloaf, mashed potatoes); and from specific cities, such as New Orleans (gumbo, jambalaya), Kansas City and Memphis (barbecue), and San Francisco (nouvelle cuisine) are advertised as culinary Others appropriate for tourism.

Time as Other refers to both past and future. Foods from the past are commonly found in museums, reenactment events, and cookbooks, and are used as a way of touring a historical era. Similarly, visions of the future can be translated into foodways—astronaut foods, freeze-dried ice cream, foods compressed into pills and vitamins. Ethos and religion as Other offer foods representing different or novel worldviews and value systems. Religions specifying food taboos or guidelines, such as Judaism, Islam, and Hinduism, can be explored as tourism by experiencing their foodways. Vegetarian foods—textured protein, veggie burgers, and foods commonly used in the United States as meat substitutes, such as bean curd and tempeh—are frequently tried out of curiosity rather than ethical belief.

Socioeconomic class is another category of Other. Gourmet foods, fine wine, and expensive restaurants are associated with the upper class, and individuals can get a taste of that lifestyle through these foodways. Conversely, foods associated with lower classes—white bread and bologna sandwiches, junk foods, processed "cheese food," opossum meat or roadkill, meager portions—can be tried in order "to see how the other half lives."

Gender represents the final Other. Although strict taboos do not exist in the United States, there are certain foods associated with each gender: women eat salads, "light" foods, poultry and fish, dainty portions; men eat red meat, large portions, hearty foods. By trying the foods associated with another gender, an individual can try out that identity.

Culinary tourism involves three realms or continua of experience: the exotic, the edible, and the palatable.

Based on the perceptions of consumers, the exotic ranges from those food experiences that are familiar and commonplace to those that are strange, new, and different. The edible-to-inedible continuum represents concepts of which items are physically, conceptually, and morally possible for ingestion. These concepts are culturally constructed but also draw upon the consumer's personal ethos. Palatable refers to pleasant and satisfying tastes, and represents individual preferences as well as social trends identifying desirable foods and designating their symbolic associations. Since the placement of foods and food experiences within these continua is a matter of perception and experience, this placement can shift over time or place and between individuals. Foods, therefore, that are perceived as appropriate for culinary tourism can become mundane and familiar, and then may be eaten out of hunger or taste preference rather than curiosity. For example, in the United States, foods that were recently touristic but have become standard fare in many American diets include Japanese sushi; Thai noodles with peanut sauce; Chinese chop suey, chow mein, and egg rolls; Mexican tacos and burritos; and Middle Eastern pita. These and other foods range in the extent of their adaptation to American tastes and resources. As these foods become more familiar, those eaters seeking more touristic experiences tend to seek more authenticity and depth of understanding of a foreign cuisine.

Food will be a part of tourism as long as people are curious about the world around them, but both are multivocal and multivalent domains of activity. And it is important to remember that although foodways can offer an entry into another realm of Other, culinary tourism is frequently not as much a window into other cultures as a mirror on our own.

## TOXINS, UNNATURAL, AND FOOD SAFETY.

Toxins may be released into the environment through industrial processes and agricultural products. These toxins are unnatural and may become harmful when they enter the food chain through crop and animal uptake.

Many agricultural products are known to contain heavy metals and other contaminants. In fact many, such as fertilizers, pesticides, fumigants, sludge, liming agents, animal feed supplements, and soil amendments, are known or are suspected to be derived from industrial waste. Waste disposed in this manner includes but is not limited to that generated by leather tanneries, steel mills, coal-fired power plants, mines, film processors, nuclear fuel processors, pulp and paper, tire incinerators, and petroleum refineries.

Little regulation and even less oversight is devoted to this method of disposal. If the waste contains just one of the macronutrients or micronutrients or if it possesses a soil-amending quality, industry can call it a product. Theoretically, anything can go into fertilizer. It is frequently contaminated with arsenic, mercury, cadmium, lead, dioxin, radionuclides, nickel, beryllium, and more. The only requirement for these wastes is that they meet the standard for disposal in a lined hazardous waste landfill. In other words, they are too toxic for standard disposal, but because of a loophole in the law, they are not too toxic for disposal on farmland. Even mined fertilizers, such as phosphate rock, may contain high levels of toxic metals.

Fertilizers, soil amendments, and liming materials are of particular concern since they are applied to agricultural soils in high volume. Over 110 billion pounds of fertilizer are land-applied each year in the United States, approximately 90 percent of it on farmland. The Environmental Protection Agency, whose charge it is to regulate hazardous waste disposal, admits that it does not know how much hazardous waste is disposed as fertilizer or the fate of these chemicals in the environment.

It is the fate of these chemicals that is cause for greatest concern. Increased soil concentrations, differing soil types, and pH levels can affect plant uptake of contaminants. Sandy soils and low pH, for example, increase plant uptake, while clay soils and high pH reduce it. Many of these contaminants have half-lives of hundreds of years and can change form in the environment as new chemicals are added. These new compounds may differ from the originals in toxicity, solubility, and plant availability.

In addition to crop uptake, these contaminants may also pollute waterways and become available for uptake

## A TOXICITY GLOSSARY

**Arsenic**—Known carcinogen. Highest concentrations are in seafood, rice and rice cereal, mushrooms, and poultry. Root crops, such as carrots, onions, and potatoes, are the most vulnerable.

**Cadmium**—Low levels are found in all foods. Largest dietary contributors are grains and cereal products. Highest levels are found in leafy vegetables, potatoes, and other root crops. Long-term exposure to low levels may cause kidney disease, cancer, lung damage, and fragile bones.

**Dioxin**—Endocrine disruptor. Causes birth defects, developmental problems, and cancer.

**Lead**—Neurotoxin. Lowers IQ and damages the immune system. Fruits, grains, cereal products, and legumes contain the highest concentrations. Fetuses and pregnant women are most at risk.

**Mercury**—Possible carcinogen. May cause brain, kidney, or fetal damage. Highest concentration is in fish. Grains and meat account for half of the dietary intake.

**Macronutrients**—Examples include nitrogen, phosphorous, potassium, sulfur, calcium, magnesium.

**Micronutrients**—Examples include boron, molybdenum, copper, manganese, zinc, selenium, iron chloride.

by other plant and animal species. Forty percent of waterway pollution is attributed to runoff. Additionally, some of these wastes, such as zinc from steel mill flue dust, are used as animal feed supplements. Animals ingest thirteen toxic metals, which concentrate in organ meats, such as liver and kidney, and dioxin, which is stored in fat.

These toxins find their way into the food supply, as documented by the Food and Drug Administration (FDA) Total Diet Study. Since 1961 the Total Diet Study has monitored the U.S. food supply for industrial contaminants, toxic elements, radionuclides, essential minerals, and pesticides. The study has found that, on a body-weight basis, infants and toddlers consume on average two to three times as much cadmium, arsenic, and mercury and three to four times as much lead as do teens and adults.

Infants, toddlers, and developing fetuses are the most vulnerable populations. Many toxins pass from the mother to the fetus, potentially altering the developing brain, nervous system, and orderly development of the body.

**TRACE ELEMENTS.** Early in the twentieth century, scientists were able to qualitatively detect small amounts of several elements in living organisms. At the time, these elements were often described as being present in "traces" or "trace amounts." This apparently led to the term "trace elements," which today is usually defined as mineral elements that occur in living systems in micrograms per gram of body weight or less. A majority of elements of the periodic table probably could be considered trace elements. However, the presence of most of these elements in higher animals quite likely is just a manifestation of our geochemical origin or the result of environmental exposure. Only eight trace elements are generally accepted as being essential for health and well-being in higher animals through the consumption of food and beverages; these are cobalt, copper, iodine, iron, manganese, molybdenum, selenium, and zinc. Persuasive evidence has recently appeared that indicates two other trace elements, boron and chromium, may also be essential; however, general acceptance of their essentiality is still lacking. Based on findings with experimental animals and lower life forms, numerous other trace elements have been suggested as being essential for higher animals including aluminum, arsenic, fluorine, lithium, nickel, silicon, and vanadium. However, conclusive evidence for essentiality, such as a defined biochemical function, is lacking for these elements. Thus, their nutritional importance remains to be determined. Of the elements mentioned, assuring the consumption of foods providing adequate amounts of iodine, iron, and zinc is of greatest practical concern for human health. Evidence is emerg-

ing, however, suggesting that the amount of cobalt (as vitamin B<sub>12</sub>), copper, selenium, boron, and chromium provided through foods should be considered a practical nutritional concern in assuring or promoting health and well-being. These eight elements will be emphasized in this review.

#### Physiological Roles of Trace Elements

Trace elements have several roles in living organisms. Some are essential components of enzymes where they attract substrate molecules and facilitate their conversion to specific end products. Some donate or accept electrons in reactions of reduction and oxidation, which results in the generation and utilization of metabolic energy. One trace element, iron, is involved in the binding, transporting, and releasing of oxygen in higher animals. Some trace elements impart structural stability to important biological molecules. Finally, some trace elements control important biological processes through such actions as facilitating the binding of molecules to receptor sites on cell membranes, altering the structure or ionic nature of membranes to prevent or allow specific molecules to enter or leave a cell, and inducing gene expression resulting in the formation of proteins involved in life processes.

#### Homeostatic Regulation of Trace Elements

The ability of the body to maintain the content of a specific substance such as a trace element within a certain range despite varying intakes is called homeostasis. Homeostasis involves the processes of absorption, storage, and excretion. The relative importance of these three processes varies among the trace elements. The homeostatic regulation of trace elements existing as positively charged cations (for example, copper, iron, zinc) occurs primarily during absorption from the gastrointestinal tract. Trace elements absorbed as negatively charged anions (for example, boron, selenium) are usually absorbed freely and completely from the gastrointestinal tract. Thus, they are homeostatically regulated primarily by excretion through the urine, bile, sweat, and breath. Storage of trace elements in inactive sites or forms is another mechanism that prevents inappropriate amounts of reactive trace elements to be present, for example, storage of iron in the form of ferritin. Release of a trace element from a storage site also can be important in preventing deficiency.

#### Iodine

This trace element has one known function in higher animals and humans; it is a constituent of thyroid hormone (thyroxine, T<sub>4</sub>) that, after conversion to triiodothyronine (T<sub>3</sub>), functions as a regulator of growth and development by reacting with cell receptors, which results in energy (adenosine triphosphate, ATP) production and the activation or inhibition of synthesis of specific proteins.

Recognition that iodine was nutritionally important began in the 1920s when it was found that iodine pre-

vented goiter, and increased iodine intake was associated with decreased endemic cretinism, the arrested physical and mental development caused by the lack of thyroid hormone. Today, the consequences of iodine deficiency still are a major public health problem in the world. In fact, iodine deficiency is the most prevalent global cause of preventable mental retardation. Briefly, the spectrum of iodine deficiency disorders is large and includes fetal congenital anomalies and perinatal mortality; neurological cretinism characterized by mental deficiency, deaf mutism, spastic diplegia (spastic stiffness of the limbs), and squint; psychomotor defects; goiter; and slowing of the metabolic rate causing fatigue, slowing of bodily and mental functions, weight increase, and cold intolerance.

Although homeostatic mechanisms allow for a substantial tolerance to high intakes of iodine, iodine-induced hyperthyroidism has been recognized for nearly two centuries. People who have had a marked iodine deficiency and are then given high amounts of iodine as part of a preventative program are at risk of getting hyperthyroidism with clinical signs including weight loss, tachycardia, muscle weakness, and skin warmth.

Iodide, an anion, is rapidly and almost completely absorbed from the stomach and upper gastrointestinal (GI) tract. Most other forms of iodine are changed in the GI tract to iodide and completely absorbed. When thyroid hormone is ingested, about 80 percent is absorbed without change; the rest is excreted in the feces. Absorbed iodide circulates in the free form; it does not bind to proteins in blood. Iodide is rapidly removed from circulation by the thyroid and kidney. Urinary excretion is a major homeostatic mechanism. If iodine intake has been adequate, only about 10 percent of absorbed iodide appears in the thyroid, the rest appears in the urine. However, if iodine status is inadequate, a much higher percentage, up to 80 percent, can appear in the thyroid. The thyroid gland is essentially the only storage site for iodine, where it appears mostly as mono- and diiodotyrosine and  $T_4$ , with a small amount of  $T_3$ .

The recommended intakes of iodine for various age and sex groups are shown in Table 1, which shows that the recommended dietary allowance (RDA) for adults is 150  $\mu\text{g}/\text{day}$ . Iodized salt has been the major method for assuring adequate iodine intake since the 1920s. Other sources of iodine are seafood and foods from plants grown on high-iodine soils.

## Iron

This trace element is a component of molecules that transport oxygen in blood. Numerous enzymatic reactions involving oxidation and reduction (redox) use iron as the agent through which oxygen is added, hydrogen is removed, or electrons are transferred. The classes of enzymes dependent on iron for activity include the oxidoreductases, exemplified by xanthine oxidase/dehydrogenase; monooxygenases, exemplified by the amino acid oxidases and cytochrome P450; dioxygenases, exempli-

fied by amino acid dioxygenases, lipoxygenases, peroxidases, fatty acid desaturases, and nitric oxide synthases; and miscellaneous enzymes such as aconitase.

Among the trace elements, iron has the longest and best described history. By the seventeenth century, a recognized treatment for chlorosis, or iron deficiency anemia, was drinking wine containing iron filings. Despite the extensive knowledge about its treatment and prevention, and the institution of a variety of effective interventions, iron deficiency is the primary mineral deficiency in the United States and the world today. The physiological signs of iron deficiency include anemia, glossitis (smooth atrophy of tongue surface), angular stomatitis (fissures at the angles of the mouth), koilonychia (spoon nails), blue sclera, lethargy, apathy, listlessness, and fatigue. Pathological consequences of iron deficiency include impaired thermoregulation, immune function, mental function, and physical performance; complications in pregnancy, including increased risk of premature delivery, low birth weight, and infant mortality; and possibly increased risk of osteoporosis.

Concerns have been expressed about high intakes of iron being a health issue. This has come about through epidemiologic observations associating high dietary iron or high body iron stores with cancer and coronary heart disease. Further experimental studies, however, are required to confirm whether the high intakes of iron increase the risk for these diseases. The toxic potential of iron arises from its biological importance as a redox element that accepts and donates electrons to oxygen that can result in the formation of reactive oxygen species or radicals that can damage cellular components such as fatty acids, proteins, and nucleic acids. Antioxidants are enzymes or molecules that prevent the formation of oxygen radicals or convert them to nonradical products. When not properly controlled by antioxidants, reactive oxygen damage can lead to premature cell aging and death. An iron overload disease known as hereditary hemochromatosis is caused by a defective regulation of iron transport with excessive iron absorption and high transferrin (transport form) iron in plasma. Clinical signs appear when body iron accumulates to about 10 times normal and include cirrhosis, diabetes, heart failure, arthritis, and sexual dysfunction. Hemochromatosis also increases the risk for hepatic carcinoma. The treatment for hereditary hemochromatosis is repeated phlebotomy.

Absorption from the GI tract is the primary homeostatic mechanism for iron. Dietary iron exists generally in two forms, heme and non-heme, that are absorbed by different mechanisms. Heme iron is a protoporphyrin molecule containing an atom of iron; it comes primarily from hemoglobin and myoglobin in meat, poultry, and fish. Non-heme iron is primarily inorganic iron salts provided mainly by plant-based foods, dairy products, and iron-fortified foods. Heme iron is much better absorbed and less affected by enhancers and inhibitors of absorption than non-heme iron. Iron absorption is regulated by

mucosal cells of the small intestine, but the exact mechanisms in the regulation have not been established. Both iron stores and blood hemoglobin status have a major influence on the amount of dietary iron that is absorbed. Under normal conditions, men absorb about 6 percent and menstruating women absorb about 13 percent of dietary iron. However, with severe iron deficiency anemia (functionally deficient blood low in hemoglobin), absorption of non-heme iron can be as high as 50 percent. Iron loss from the body is very low, about 0.6 mg/day. This loss is primarily by excretion in the bile and, along with iron in desquamated mucosal cells, eliminated via the feces. Menstruation is a significant means through which iron is lost for women. It should be noted, however, that nonphysiological loss of iron resulting from conditions such as parasitism, diarrhea, and enteritis account for half of iron deficiency anemia globally. Excess iron in the body is stored as ferritin and hemosiderin in the liver, reticuloendothelial cells, and bone marrow.

The recommended intakes of iron for various age and sex groups are shown in Table 1, which shows that the RDA for adult males and postmenopausal women is 8 mg/day; and that for menstruating adult women is 18 mg/day. Meat is the best source of iron, but iron-fortified foods (cereals and wheat-flour products) also are significant sources.

## Zinc

This trace element is the only one that is found as an essential component in enzymes from all six enzyme classes. Over 50 zinc metalloenzymes have been identified. Zinc also functions as a component of transcription factors known as zinc fingers that bind to DNA and activate the transcription of a message, and imparts stability to cell membranes.

Signs of zinc deficiency in humans were first described in the 1960s. Although it is generally thought that zinc deficiency is a significant public health concern, the extent of the problem is unclear because there is no well-established method to accurately assess the zinc status of an individual. The physiological signs of zinc deficiency include depressed growth; anorexia (loss of appetite); parakeratotic skin lesions; diarrhea; and impaired testicular development, immune function, and cognitive function. Pathological consequences of zinc deficiency include dwarfism, delayed puberty, failure to thrive (acrodermatitis enteropathica infants), impaired wound healing, and increased susceptibility to infectious disease. It has also been suggested that low zinc status increases the susceptibility to osteoporosis and to pathological changes caused by the presence of excessive reactive oxygen species or free radicals.

Zinc is a relatively nontoxic element. Excessive intakes of zinc occur only with the inappropriate intake of supplements. The major undesirable effect is an interference with copper metabolism that could lead to cop-

per deficiency. Long-term high zinc supplementation can reduce immune function and high-density lipoprotein (HDL)-cholesterol (the "good" cholesterol). These effects are seen only with zinc intakes of 100 mg/day or more.

A primary homeostatic mechanism for zinc is absorption from the small intestine. Absorption involves a carrier-mediated component and a nonmediated diffusion component. With normal dietary intakes, zinc is absorbed mainly by the carrier-mediated mechanism. Although absorption can be modified by a number of factors, about 30 percent of dietary zinc is absorbed. The efficiency of zinc absorption is increased with low zinc intakes. The small intestine has an additional role in zinc homeostasis through regulating excretion through pancreatic and intestinal secretions. After a meal, greater than 50 percent of the zinc in the intestinal lumen is from endogenous zinc secretion. Thus, zinc homeostasis depends upon the reabsorption of a significant portion of this endogenous zinc. Intestinal conservation of endogenous zinc apparently is a major mechanism for maintaining zinc status when dietary zinc is inadequate. The urinary loss of zinc is low and generally not markedly affected by zinc intake.

The recommended intakes of zinc for various age and sex groups are shown in Table 1, which shows that the RDA for adult males is 11 mg/day and for adult females is 8 mg/day. The best food sources for zinc are red meats, organ meats (for example, liver), shellfish, nuts, whole grains, and legumes. Many breakfast cereals are fortified with zinc.

## Cobalt (Vitamin B<sub>12</sub>)

Ionic cobalt is not an essential nutrient for humans. Cobalt is an integral component of vitamin B<sub>12</sub>, which is an essential nutrient for nonruminant animals and humans. Vitamin B<sub>12</sub> is a cofactor for two enzymes, methionine synthase which methylates homocysteine to form methionine, and methylmalonyl coenzyme A (CoA) mutase which converts L-methylmalonyl CoA, formed by the oxidation of odd-chain fatty acids, to succinyl CoA.

In the nineteenth century, a megaloblastic anemia (functionally deficient blood containing primitive large red blood cells) was identified that was invariably fatal and thus called pernicious anemia. The first effective treatment for this disease was 1 pound of raw liver daily. In 1948, the anti-pernicious anemia factor (vitamin B<sub>12</sub>) in liver was isolated and found to contain 4 percent cobalt. Vitamin B<sub>12</sub> deficiency most commonly arises when there is a defect in vitamin B<sub>12</sub> absorption caused by such factors as atrophic gastritis, *Helicobacter pylori* infection, and bacteria overgrowth resulting from achlorohydria and intestinal blind loops. Because vitamin B<sub>12</sub> only comes from foods of animal origin, absolute vegetarianism will lead to deficiency in vitamin B<sub>12</sub> after 5 to 10 years. The physiological signs of severe vitamin B<sub>12</sub> deficiency are megaloblastic anemia, spinal cord demyelination, and pe-

TABLE 1

**Recommended Dietary Allowances for Selected Trace Elements Established by the Food and Nutrition Board, Institute of Medicine, National Academy of Sciences (see bibliography).**

	Recommended Dietary Allowance					
	Copper ( $\mu\text{g/day}$ )	Iodine ( $\mu\text{g/day}$ )	Iron ( $\text{mg/day}$ )	Selenium ( $\mu\text{g/day}$ )	Vitamin B <sub>12</sub> (cobalt) ( $\mu\text{g/day}$ )	Zinc ( $\text{mg/day}$ )
0–6 months	—	—	—	—	—	—
7–12 months	—	—	11	—	—	3
1–3 years	340	90	7	20	0.9	3
4–8 years	440	90	10	30	1.2	5
9–13 years	700	120	8	40	1.8	8
14–18 years	890	150	11 M/15 F	55	2.4	11 M/9 F
19–50 years	900	150	8 M/18 F	55	2.4	11 M/9 F
51 years and greater	900	150	8	55	2.4	11 M/8 F
Pregnancy						
18 years or less	1,000	220	27	60	2.6	13
19–50 years	1,000	220	27	60	2.6	11
Lactation						
18 years and less	1,300	290	10	70	2.8	14
19–50 years	1,300	290	9	70	2.8	12

Abbreviations: F, female; M, male.

ripheral neuropathy. The pathological consequences of deficiency include pernicious anemia, memory loss, dementia, an irreversible neurological disease called subacute degeneration of the spinal cord, and death. Recently, mild vitamin B<sub>12</sub> deficiency has been cited as a cause of high circulating homocysteine, which has been associated with an increased risk for cardiovascular disease. Vitamin B<sub>12</sub> is essentially nontoxic. Doses up to 10,000 times the minimal daily adult human requirement do not have adverse effects.

Vitamin B<sub>12</sub> absorption is a relatively complex process. Digestion by the saliva and acid environment of the stomach releases vitamin B<sub>12</sub> from food, then it is bound to a haptocorrin called R protein that carries it into the duodenum. A binding protein, called intrinsic factor, released by gastric parietal cells binds vitamin B<sub>12</sub> after the stomach acid is neutralized in the duodenum, and digestive enzymes remove the R binder from the vitamin. The intrinsic factor-bound vitamin B<sub>12</sub> is carried to a specific receptor in the ileum called cubilin and internalized by receptor-mediated endocytosis. Because vitamin B<sub>12</sub> is water-soluble, excessive intakes are efficiently excreted in the urine.

The recommended intakes for vitamin B<sub>12</sub> for various age and sex groups are shown in Table 1, which shows that the RDA for adults is 2.4  $\mu\text{g/day}$ . Food sources of vitamin B<sub>12</sub> are of animal origin and include meats, dairy products, and eggs. Fortified cereals have also become a significant source of vitamin B<sub>12</sub>.

## Copper

Copper is a cofactor for a number of oxidase enzymes including lysyl oxidase, ferroxidase (ceruloplasmin), dopamine beta-monooxygenase, tyrosinase, alpha-amidating monooxygenase, cytochrome C oxidase, and superoxide dismutase. These enzymes are involved in the stabilization of matrixes of connective tissue, oxidation of ferrous iron, synthesis of neurotransmitters, bestowal of pigment to hair and skin, assurance of immune system competence, generation of oxidative energy, and protection from reactive oxygen species. Copper also regulates the expression of some genes.

Although copper is a well-established essential trace element, its practical nutritional importance is a subject of debate. Well-established pathological consequences of copper deprivation in humans have been described primarily for premature and malnourished infants and include a hypochromic, normocytic, or macrocytic anemia; bone abnormalities resembling scurvy by showing osteoporosis, fractures of the long bones and ribs, epiphyseal separation, and fraying and cupping of the metaphyses with spur formation; increased incidence of infections; and poor growth. The consequences of the genetic disorder Menkes' disease (copper deficiency caused by a cellular defect in copper transport) in children include "kinky-type" steely hair, progressive neurological disorder, and death. Other consequences have been suggested based upon findings from epidemiological studies, and animal and short-term human copper deprivation experiments;

these include impaired brain development and teratogenesis for the fetus and children, and osteoporosis, ischemic heart disease, cancer, increased susceptibility to infections, and accelerated aging for adults.

Copper toxicity is not a major health issue. The ingestion of fluids and foods contaminated with high amounts of copper can cause nausea. Because their biliary excretion pathway is immature, accumulation of toxic amounts of copper in the liver could be a risk for infants if intake is chronically high; this apparently caused cases of childhood liver cirrhosis in India.

Intestinal absorption is a primary homeostatic mechanism for copper. Copper enters epithelial cells of the small intestine by a facilitated process that involves specific copper transporters, or nonspecific divalent metal ion transporters located on the brush-border surface. Then the copper is transported to the portal circulation where it is taken up by the liver and resecreted in plasma bound to ceruloplasmin. Transport of copper from the liver into the bile is the primary route for excretion of endogenous copper. Copper of biliary origin and nonabsorbed dietary copper are eliminated from the body via the feces. Only an extremely small amount of copper is excreted in the urine. The absorption and retention of copper varies with dietary intake and status. For example, the percentages of ingested copper absorbed were 56 percent, 36 percent, and 12 percent with dietary intakes of 0.8, 1.7, and 7.5 mg/day, respectively. Moreover, tissue retention of copper is markedly increased when copper intake is low.

The recommended intakes for copper for various ages and sex groups are shown in Table 1, which shows that the RDA for adults is 900  $\mu\text{g/day}$ . The best sources of copper are legumes, whole grains, nuts, organ meats (for example, liver), seafood (for example, oysters, crab), peanut butter, chocolate, mushrooms, and ready-to-eat cereals.

## Selenium

Selenium is a component of enzymes that catalyze redox reactions; these enzymes include various forms of glutathione peroxidase, iodothyronine 5'-deiodinase, and thioredoxin reductase.

Although selenium was first suggested to be essential in 1957, this was not firmly established until a biochemical role was identified for selenium in 1972. The first report of human selenium deficiency appeared in 1979; the subject resided in a low-selenium area and was receiving total parenteral nutrition (TPN) after surgery. The subject and other selenium-deficient subjects on TPN exhibited bilateral muscular discomfort, muscle pain, wasting, and cardiomyopathy. Subsequently, it was discovered that Keshan disease, prevalent in certain parts of China, was prevented by selenium supplementation. Keshan disease is a multiple focal myocardial necrosis resulting in acute or chronic heart function insufficiency,

heart enlargement, arrhythmia, pulmonary edema, and death. Other consequences of inadequate selenium include impaired immune function and increased susceptibility to viral infections. Selenium deficiency also can make some nonvirulent viruses become virulent.

Recently, however, not only selenium deficiency, but effects of supranutritional intakes of selenium have become of great health interest. Several supplementation trials have indicated that selenium has anticarcinogenic properties. For example, one trial with 1,312 patients supplemented with either 200  $\mu\text{g}$  selenium/day or with a placebo found the selenium treatment was statistically associated with reductions in several types of cancer including colorectal and prostate cancers.

Selenium is a relatively toxic element; Intakes averaging 1.2 mg/day can induce changes in nail structure. Chronic selenium intakes over 3.2 mg/day can result in the loss of hair and nails, mottling of the teeth, lesions in the skin and nervous system, nausea, weakness, and diarrhea.

Selenium, which is biologically important as an anion, is homeostatically regulated by excretion, primarily in the urine but some also is excreted in the breath. Selenate, selenite, and selenomethionine are all highly absorbed by the GI tract; absorption percentages for these forms of selenium are commonly found to be in the 80 to 90 percent range.

The recommended intakes for selenium are shown in Table 1, which shows that the RDA for adults is 55  $\mu\text{g/day}$ . Food sources of selenium are fish, eggs, and meat from animals fed abundant amounts of selenium and grains grown on high-selenium soil.

## Boron

Recent findings with this trace element suggest that it may be of nutritional importance, although a clearly defined biochemical function for boron in higher animals and humans has not been defined. It has been hypothesized, however, that boron has a role in cell membrane function that influences the response to hormones, transmembrane signaling, or transmembrane movement of regulatory cations or anions. Human studies suggest that a low boron intake can impair cognitive and psychomotor function and the inflammatory response, as well as increasing the susceptibility to osteoporosis and arthritis.

About 85 percent of ingested boron is absorbed and excreted in the urine shortly after ingestion. Because boron homeostasis is regulated efficiently by urinary excretion, it is a relatively nontoxic element. A tolerable upper level intake of 20 mg/day was determined for boron by the Food and Nutrition Board of the United States National Academy of Sciences.

An analysis of both human and animal data by a World Health Group suggested that an acceptable safe range of population mean intakes for boron for adults

could be 1 to 13 mg/day. Foods of plant origin, especially fruits, leafy vegetables, nuts, pulses, and legumes are rich sources of boron.

### Chromium

A naturally occurring biologically active form of chromium called chromodulin has been described that apparently has a role in carbohydrate and lipid metabolism as part of a novel insulin-amplification mechanism. Chromodulin is an oligopeptide that binds four chromic ions and facilitates insulin action in converting glucose into lipids and carbon dioxide.

The nutritional importance of chromium is currently a controversial subject. Chromium deficiency has been suggested to impair glucose tolerance, which could eventually lead to diabetes. Supranutritional chromium supplementation (1,000  $\mu\text{g/day}$ ) has been found beneficial for some cases of type II diabetes. Supplements containing supranutritional amounts of chromium in the picolinate form have been promoted as being able to induce weight loss and to increase muscle mass. However, most ergogenic (work output) oriented studies have found chromium picolinate supplementation to be ineffective for increasing muscle mass, strength, and athletic performance, and there are no data from well-designed studies to support the claim that chromium picolinate supplementation is an effective weight loss modality. Chromium in the +3 valence state is a relatively non-toxic element.

Chromium homeostasis is regulated by intestinal absorption, which is low. Estimates of absorption range from less than 0.5 to 2 percent. Absorbed chromium is excreted in the urine.

The Food and Nutrition Board of the United States Academy of Sciences determined that there was not sufficient evidence to set an estimated average requirement of chromium. Therefore, an adequate intake was set based on estimated mean intakes. The adequate intake for young males was set at 35  $\mu\text{g/day}$ , and that for young females was set at 25  $\mu\text{g/day}$ . Some of the best food sources of chromium are whole grains, pulses, some vegetables (for example, broccoli and mushrooms), liver, processed meats, ready-to-eat cereals, and spices.

### Conclusion

It is likely that not all the essential mineral elements for humans have been identified. Moreover, numerous biochemical functions for trace elements most likely remain to be identified. Thus, the full extent of the pathological consequences of marginal or deficient intakes of the trace elements has not been established. Furthermore, some trace elements such as selenium, fluoride, and lithium in supranutritional amounts are being found to have therapeutic or preventative value against disease. Thus, the determination of the importance of trace elements for human health and well-being should be considered a

work in progress with some exciting advances likely in the future.

**TRAVEL.** During the course of history, the impact of travel on the relationship between food and man has been manifold. Encounters with new foods have often caused reactions of dissociation or of rejection—not only of the foods themselves, but also of the people eating them. The widespread idea that the food consumed by a group of people is closely connected with their level of civilization has been a way to express and underscore differences between neighboring populations. Food being an inoffensive category, it readily lends itself to becoming a means of distinguishing between "us and them," both geographically, in relation, for instance, to regions or countries, and socially, setting "us" apart from people within the same region we consider to be at a lower level in the social hierarchy.

Food habits are closely linked to a person's conception of identity. The acceptance of different foodstuffs, or their avoidance—taste or distaste—is a mixture of cultural conditioning and personal idiosyncrasies. It is natural, therefore, that the food consumed by one's own group is considered to be the "proper food," whereas the food of the others encountered during one's travels is accepted with some reluctance. Foods associated with a higher status are more easily adopted, as are those associated with lifestyles one wishes to share.

Obviously the reason for traveling will have some bearing on the attitude toward the food encountered.

American railroad fare is not much better today than in the nineteenth century. Travelers on the Chesapeake & Ohio line were obliged to buy their bad coffee, railroad cakes, hardtack, and Sally Luns from vendors who congregated at stations along the way. FROM JOHN BACHELDER'S *POPULAR RESORTS* (BOSTON, 1875). ROUGHWOOD COLLECTION.

People who have been forcibly displaced (through war, disasters, slavery [but see below], economic hardships, or religious persecution) are more likely to maintain earlier food habits, where possible—partly through lack of means, partly from nostalgia for a lifestyle that has been lost. If, on the other hand, travel is undertaken on a voluntary basis, especially for pleasure (most notably tourism), people are more likely to try new foods.

Historically, little is known about travelers' food. It may be said that in general those who could took their food (and even people in charge of preparing it) with them, which meant that they tried to emulate their usual food habits. Others would make do with the local fare at wayside inns or the tables of hospitable notables. After the emergence of restaurants at the beginning of the nineteenth century in Europe, an internationalized bourgeois cuisine became available to travelers. Regional cooking did not start to come into focus for the general public until the period between the two World Wars, alongside the emergence of automobile tourism. And only recently has local and regional food become a focus of scientific as well as of touristic discourse. To better understand the role of food in travel one needs to distinguish different categories of travelers. Professional travelers of the past, such as sailors and military men, would in the main take their own food with them; however, at the same time, they were often adventurers and would typically experi-

ence extremely foreign foods, though they would only rarely bring these back with them.

In many instances on the other hand, food became the very reason for travel: explorers set out from Europe to reach the homelands of desirable foods, particularly spices. In a second phase, explorers were followed by tradesmen, civilian officials, and others establishing colonies on other continents. From these activities came sugar, tea, coffee, and many fruits, vegetables, and grains (for example, pineapples, potatoes, and rice), now everyday commodities in the Western world. Their history is intertwined with that of major empires. In some cases, myths have been constructed around them (for instance, the one claiming that Marco Polo brought pasta to Italy from China—belied by the fact that there was a flourishing commerce of pasta in the Mediterranean before the time of his travels). The rise and fall of food trends is clearly reflected in more general world history, as exemplified by the passion for spices in the Middle Ages and Renaissance leading to journeys of exploration, or the court culture of Italy and France, which, through traveling notables, influenced the food habits in many European countries from the sixteenth century onward.

For immigrants, the acquisition of new food habits is dependent on the time spent in the new environment (usually it is a matter of generations). As for any traveler, the reaction to the different food habits experienced will be related to the scope and duration of the travel. A special case is that of the American Pilgrims adopting the food of Native Americans, with the event evolving into a national commemorative meal: the Thanksgiving dinner. On the other hand, the slaves brought to America from Africa, who had no possibility of either maintaining their own food habits or having a free choice among those they met in the new country, have developed a very different symbolic food: soul food.

However, food habits may also be affected in the opposite direction. Colonies of foreign nationals have introduced new items in the diet of the new environment. Thus, for example, in the Middle Ages, gingerbread spread throughout Europe with German immigrants, and more recently Chinese food has become a familiar food in Western countries. Following the rise of charter tourism in the 1950s, pizza and pasta started to become a familiar food in many countries outside Italy, having in some places even replaced potatoes as an everyday staple food.

During the second half of the twentieth century, food began to play a significant role in tourism. In the meeting with the unfamiliar that takes place during travel, food plays a central role, since everybody has to eat every day, and so the deviation from what is habitual and accepted cannot be avoided or disregarded. Travel thus brings about an awareness of differences between the self (the learned and shared culture at home) and others (notably, their culture and habits), as it forces the individual to venture into the realm of sensory experiences that belong to the others. In parallel with the increased move-

ment of people we see in recent times, the establishment of international restaurants and sale of foreign foodstuffs means one no longer needs to travel to experience foreign foods. This highlights some of the paradoxes of the international world today, where tourists may oscillate between the attraction of what represents “other” and adventure, and the unchallenging ease of familiarity and security. Tourists typically want to escape boredom, but to do so while staying within their comfort zone.

Renée Valeri

**TRUFFLES.** See **France**.

**TUBERS.** Tuber is a loan word deriving from the Latin verb *tumere* (to swell). It was introduced into colloquial English via botanical Latin during the Renaissance and retains a number of related meanings: a swelling, a growth resembling a knot, or even a truffle. When applied to vegetables, tuber is now understood to mean a fleshy underground swelling on root strands that normally contains varying proportions of starch. In reality, this definition is quite imprecise given the huge diversity of tuberous-like roots and stems that exist in nature.

For example, taro (*Colocasia sp.*), is sometimes referred to as a tuber and sometimes as a corm since it straddles the definition of both. Other vegetables, like the arracacha (*Arracacha xanthorrhiza*) of South America, are often classified as “tuberous rooted” since the swollen part is not distinctly separate from the crown or herbaceous (above-ground) parts of the plant. The potato is considered a classic example of a common tuber, since the swollen part forms along various root strands and is only connected to the rest of the plant in this fashion. However, it is possible to induce this feature in any number of wild tuberous-rooted plants once domesticated and carefully selected.

Most true tubers are capable of reproducing themselves vegetatively and when reproduced in this manner, they become true genetic clones of their parents. This reproduction technique allows beneficial characteristics, such as flavor, texture, storing qualities, or resistance to certain pests and diseases to be preserved from one generation to the next. It would appear, however, that most tubers originally appealed to humans for their starch or sugars, especially tubers that could be consumed raw. Only later did cookery expand the list of choices, since many tubers like cassava are toxic until exposed to heat or some other processing step.

Nutrient rich and relatively easy to gather, tubers have played a major role in the history of human diet,

since they could be collected from the wild and stockpiled against times of food shortage. This dietary shift from happenstance to organized gathering, which required calculations regarding collection, storage, and distribution, brought about profound changes in human social organization and development, even more so after tubers were brought under cultivation.

Pre-agricultural societies relied heavily on foraged tubers, especially those that required little or no processing. Bog potatoes or groundnuts (*Apios tuberosa*) supplied the hunter-gatherers of eastern North America with an easy to collect source of small, starchy tubers that could be stored in pits for later use and eaten like nuts. Even for societies that later turned to intensive agriculture, such wild tubers remained an important supplement to the diet. However, many tuberous vegetables like the water parsley (*Oenanthe sarmentosa*) and wood sunflower (*Helianthus strumosus*) of North America, the bagana (*Amorphophallus abyssinicus*) of Ethiopia, and the kudzu (*Pueraria lobata*) of New Guinea, were never brought under cultivation by the native peoples of those areas, but simply gathered from the wild and traded, or allowed to grow in patches kept free of competing weeds. These managed plants were the preliminary steps toward gardening and primitive agriculture.

There is no precise record of when the first tubers were brought under cultivation on an organized basis, but in all likelihood the taros of India (if we allow that *Colocasia* and *Alocasia* are tubers) were among the first since they are mentioned in Sanskrit sources and terms for them are known in pre-Sanskrit languages. Doubtless they were followed or even preceded by potatoes in the high Andes, the yam bean (*Pachyrhizus erosus*) in Central America, and the chufa (*Cyperus esculentus*) of the Mediterranean region. Vestiges of many tuberous plants have been found in caves, but this does not mean they were cultivated. Unless there are corroborating written records, or artifacts depicting tuberous vegetables, archaeology cannot safely establish that a tuber was in fact cultivated since traces of pollen, preserved seeds, or actual dried tubers can originate from wild as well as cultivated sources. Furthermore, even where there are physical depictions of the plant, as in the case of chufa and coco grass (*Cyperus rotundus*) in ancient Egyptian paintings of pleasure gardens, this only proves that they were appreciated as ornamentals.

Yet, over time, many tuberous vegetables were indeed brought under cultivation in order to increase the supply and the reliability of the harvest. The highest percentage of indigenous cultivated tubers of different species is found in South America, where there is presently a concerted attempt to analyze and promote their uses. Elsewhere, many tubers gathered from the wild have fallen into neglect even where this nutritional diversity supplied a more balanced diet. Additionally, except for the Pacific islands, almost all of the lesser sorts of cultivated yam, such as the White Yam (*Dioscorea*

*rotundata*), and the Buck Yam (*Dioscorea pentaphylla*), have decreased in production because of the introduction of commercially improved sweet potatoes. No tubers have done more than the potato and sweet potato (*Ipomoea batatas*) to alter human agriculture and diet, since both of these plants can be grown in a wide variety of soils and microclimates on a large commercial scale.

In the tropics, however, taros and yams (*Dioscorea* sp.) remain key food crops, followed by the New World cassava (*Manihot esculenta*) and to a limited extent malanga or yautia (*Xanthosoma* sp.). Consumption patterns vary from country to country and from one cultural group to the next, and practical growing considerations should not be overlooked. For example, in some areas, cassava and malanga have become important agricultural supplements since they will grow where taro will not and like sweet potatoes, they yield a ready supply of nutritionally rich greens. Since the 1500s, Old and New World tubers have moved out of their original habitats to such an extent that there is often a great deal of confusion as to where the plants came from. The inventory that follows deals with tubers based on their continent of origin, but with brief comments on how they have spread to other parts of the world, or how they are employed in local cuisines.

### Africa (Sub-Sahara)

When we consider that yams, taros, sweet potatoes, and cassava are all exotics introduced from other continents, the range of indigenous tuberous vegetables available to Africans is extremely small. The African landscape is rich in leafy vegetables, but until the introduction of yams about 1000 C.E., there was no large tuberous vegetable serving as a staple on a continent-wide scale. Only here and there, locally occurring tubers provided limited food supplies for those willing to gather them. Most of Africa's indigenous tubers are small in size and few of them have ever been brought under cultivation. Furthermore, to date, there are no complete continent-wide inventories of native tuberous plants, a task made doubly difficult because of so many common synonyms that exist in the numerous languages of Africa, not to mention the political instability in several key countries.

While there has been a large amount of research devoted to African foodways and tribal cultures, little has been devoted to traditional gardening. The growing, gathering, and cooking of traditional plants is largely a woman's task in Africa, and in the past, this has been treated as an activity of low status. Fortunately, there is now a shift of interest in promoting the conservation and use of underutilized and neglected foods, particularly in Botswana, Ethiopia, Kenya, and Nigeria.

Many of the native tubers listed below are presently being inventoried for study and evaluation for possible breeding programs in conjunction with sustainable agriculture. However, very few of them are mentioned in cookbooks. Aside from these, *Arisaema schimperianum*,

*Campanula edulis*, *Commelina benghalensis* and *latifolia*, *Cyperus esculentus*, *Dioscorea quartiniana*, and *Dioscorea schimperiana* all provide a source of indigenous tubers that are collected from the wild in several parts of Africa.

**African yam bean (*Sphenostylis stenocarpa*).** This plant produces protein-rich seeds, edible leaves, and a large spindle-shaped tuber that can be cooked like a potato. The yam bean is mostly consumed by villagers in West Africa and even appears in cookbooks from that region.

**Anchote (*Coccinia abyssinica*).** This perennial occurs as a wild vine in several parts of East Africa. The small tubers are cooked like potatoes in Ethiopia. *Coccinia grandis* and *Coccinia triloba*, both relatives of anchote, are gathered by some tribes in Kenya.

**Hausa potato (*Solenostemon rotundifolius*).** Formerly classified *Coleus rotundifolius*, these black tubers are prepared like potatoes and may be eaten either raw or cooked. This plant has been introduced into Southeast Asia, where it is employed in curries or eaten with coconuts.

**Jacob's Coat or Sayabana (*Coleus blumei*).** Both the leaves and tubers are eaten. The leaves are also added to fermented beverages. Now introduced into tropical Asia.

**Livingstone potato (*Coleus parviflorus*).** Also known as the country potato and African potato, this handsome tuber is widely cultivated in the dry regions of East and West Africa. The tubers resemble the crosnes of east Asia, but have yellow skin and white flesh. They are also dried and then ground to make a flour for dumplings. The Arabs are thought to have introduced this into India. From there the Portuguese introduced it into Malaysia and Indonesia.

**Serendipity berry (*Dioscoreophyllum cumminsii*).** Known as *utobili* in Nigeria, this shrub produces a number of products useful to the native peoples of West Africa. The tubers are employed in soups, especially as thickeners and are considered one of the distinctive ingredients in regional Nigerian cookery.

### Eurasia (Including the Mediterranean Basin and Pacific Islands)

The Eurasian land mass represents a huge diversity of tuberous plants, and some of the earliest ones brought into cultivation. This includes all the cultivated taros (two species each of *Alocasia* and *Colocasia*, one species of *Cyrtosperma*), most of the agricultural yams (roughly ten species out of 600), and innumerable lesser tubers such as the kudzu (*Pueraria lobata*), which has become an invasive pest in the southern part of the United States. Historical information on many of the tubers from this part of the world is good, since their cultivation is often noted in the records left by peoples residing in ancient China, India, the Near East and Mediterranean Basin. It should

be noted, however, that most of the Eurasian staple tubers are of tropical origin.

**Adder's grass (*Dactylorhiza maculata*).** This is technically an orchid whose tuber was ground to yield a starchy powder employed in the preparation of *salep*. *Salep*, a word of Turkish and ultimately of Arabic origin, was a beverage served cold during hot weather and hot during cold weather. The actual drink is of Byzantine origin (or perhaps even Lydian as some historians have suggested), since the orchid tubers with which it is made are found primarily in Asia Minor and Armenia. The starch was also used to thicken milk and more recently to make a line of elastic ice creams popular in the Middle East.

Historically, salep was also popular in seventeenth- and eighteenth-century England and America, especially in coffeehouses, but in general it was regarded as a health drink. It was also thought to contain aphrodisiac qualities. It has been replaced by cornstarch or arrowroot.

**Asphodel (*Asphodeline lutea*).** A native of the Mediterranean, the Egyptians, Greeks, and Romans prepared it like a potato. It prefers sandy soil and was probably a minor crop in some parts of North Africa during classical antiquity. It also yields a starch that was highly valued as a food thickener for making medieval blancmanges, sauces, and thickened soups.

**Chufa (*Cyperus esculentus*).** Chufa is found throughout the Mediterranean Basin and in parts of sub-Saharan Africa. It has been taken to most parts of the world where it is either maintained as a garden plant or has managed to escape into the wild (as in the case of North America). Wild chufa, which is often called nut grass in English speaking countries, produces small tubers resembling brown shriveled peas. Their flavor is similar to almonds and when pressed, they yield an oil similar to almond milk. The tubers of cultivated chufa are much larger, sometimes the size of a lima bean, and much easier to employ in cookery.

Chufa was domesticated thousands of years ago and was probably an important food source for the ancient Phoenicians. The Egyptians grew it both for its ornamental leaves and its tubers. The Byzantine Greeks used it both in cookery and medicine. It is still employed in modern Spain in the preparation of *horchata*, a milky beverage popular in the fall. The British Isle imitation was called orgeat in eighteenth century cookbooks.

**Crosnes (*Stachys affinis*).** Generally harvested during the winter months when the tops are dead, the tubers are knobby and white. The plant resembles nettle and prefers moist, shady soil; thus, it is ideal for marginal ground. It is also extremely hardy, and has been cultivated as an important supplement crop in China and Japan for many centuries. The tubers are pickled or eaten in stir-fries. The plant was introduced into France in the 1880s and takes its European name from the village of Crosnes (Seine-et-Oise), the site of a large experimental farm

Crosnes (*Stachys affinis*) is a tuberous rooted relative of mint native to Asia. The nutty tubers are extremely popular in China and Japan both in stir-fries and pickles. The plant was introduced into Europe in the early 1880s and takes its name from the village of Crosnes, France, where it was first grown. PHOTO BY L. WILBUR ZIMMERMAN. ROUGHWOOD SEED COLLECTION.

where crosnes were first trialed. Crosnes are also grown in the United States and are now commonly seen in farm markets.

**Devil's tongue (*Amorphophallus rivieri*).** A native of Southeast Asia that is now very important in Japanese and Korean cooking, the tubers yield a starch that is solidified into a gel called *konnyaku* (yam cake). Noodles called *shirataki* are made from this. Yam cake is also commonly added to Korean hot-pot dishes.

**Elephant's foot or telinga potato (*Amorphophallus campanulatus*).** Mentioned in Sanskrit, this is one of the most ancient cultivated plants of tropical Asia. In India, the tuber (also called a corm) is prepared in curries, fried, added to stews, and cooked in syrup. It is also sold in cans and is imported in this form to the United States. The plant is now cultivated in East Africa, especially in areas where Indians have settled.

**Giant swamp taro (*Cyrtosperma camissonis*).** A native of the Pacific Islands and Indonesia. It grows well on the difficult soils of coral atolls, thus it is much favored by Polynesians. The tuber requires several years to mature, so cultivation is continuous, with some being dug while others are being planted.

**Kembang Bangké (*Amorphophallus variabilis*).** A near relative of devil's tongue mentioned above, this is also used to make the starchy gel known as *konnyaku*.

**Korean bellflower root (*Platycodon grandiflorus*).** This is the east Asian counterpart of the European ram-  
pion. Called *toraji* in Korean, is it employed in stir-fries and kimchee, or pickled like crosnes.

**Kudzu (*Pueraria lobata*).** Kudzu originates in China and Japan, and its common name is of Japanese origin.

It grows wild in the grasslands of the Pacific Islands, and because all parts of the plant are edible, it was formerly important in the agriculture of India, Malaysia, and Southeast Asia. Because the tubers, which can reach a length of three feet (1 meter) require several years to mature, the plant is slowly losing ground to sweet potatoes as a staple even though the tubers contain roughly 27 percent starch. The vines grow anywhere from 24 (8 meters) to 36 feet (12 meters) in one season and will overwhelm any plants nearby.

**Polynesian Arrowroot or Tacca (*Tacca leontopetaloides*).** Grown mostly on the Pacific Islands, this is an ancient source of starch, which has long been sold under the name of pia flour. The plant is cultivated throughout Oceania as well as in India and Sri Lanka. Cultivation is now declining in favor of cassava, which is easier to grow.

**Rampion (*Campanula rapunculus*).** The tubers resemble tiny potatoes and were once popular in salads and as a table vegetable. It is still cultivated to some extent in France, Germany, and Switzerland. Historically, it was grown as a garden vegetable even during Roman times, with the center of cultivation in the Rhine Valley. Its Latin name means little turnip, and it was evidently an important food among the Gauls and early Germans, perhaps with some now lost sacred connections. Numerous folk legends survive dealing with personifications of this tuber, including the famous Grimm fairy tale about Rapunzel, and the story of the first king and queen of ancient Poland—the queen’s name was rampion.

**Soldier orchid (*Orchis militaris*).** Found in temperate regions of Europe and Asia, this tuber was often gathered and prepared like a small potato. It was also used in medicine and in the preparation of *salep* (see adder’s grass). Because the tubers resemble testicles, they were thought to enhance male sexuality. As the common name implies, the tuber was often employed as a forage food by armies on the move.

**Taro (*Colocasia sp.*).** This group of tubers includes two cultivated species as well as the closely related genus *Alocasia*, all of which appear to originate in southern India. Some Indian historians claim that taro was brought under cultivation over 10,000 years ago, although this is not firmly established. Whatever the date, it is clear that taro is one of the most ancient of the cultivated Old World tubers. It spread to Egypt by the first century C.E. and then to many parts of the Mediterranean. The Spanish and Portuguese brought it to the New World. The history of taro and its many forms is taken up in further detail below.

**Yam (*Dioscorea sp.*).** Yam is a loose term covering some 600 species, of which about ten are cultivated for food. Many member of this genus are poisonous or require processing to remove toxins in order to make them safe for consumption. The common name derives from a West African word *nyami*, but the botanical origin is

thought to be Sri Lanka or Southeast Asia. Since this is such a large and economically important group, yams are treated separately below. Yams are now found in tropical regions throughout the world.

#### **North America (United States and Canada)**

In terms of naturally occurring and domesticated native tubers, North American biodiversity is relatively sparse. Most of the edible tuberous plants that exist here were employed by native populations prior to European contact. Very few of these plants were acculturated by Europeans except under frontier conditions or during times of scarcity. The introduction of the sweet potato in the South and the potato in cooler parts of the continent more or less preempted the domestication of potentially important native tuber crops that might offer nutritional alternatives better adapted to soil and climate. Only the Jerusalem artichoke (*Helianthus tuberosus*) has played a minor role doubtless because of its similarity to the potato when cooked. The following list is by no means complete, but it does list the primary tubers known to native peoples.

**Arrowhead (*Sagittaria sagittifolia*).** Found all over continental United States and Canada, it is known by many Indian names, the most common being wapattoo. The tuber tastes like a potato and can be sun-dried for use in the winter. A closely related species, sessile-fruited arrowhead (*Sagittaria rigida*) is found only in the eastern North America. Both plants are aquatic. It is also important to note here that European and Asian arrowhead, formerly treated as separate species, are now grouped together, thus this plant is in fact found throughout the Northern Hemisphere.

**Bush morning glory (*Ipomoea leptophylla*).** A native of the Great Plains, this was once collected for its tuber, which resembles a sweet potato. The tuber has also been classified as a root, although the distinction here is hazy. Some plants produce unpleasantly bitter or tough tubers, while others are starchy or even pleasantly sweet. These differences may be environmental. The tuber may be eaten raw or cooked and is excellent when sliced and sun-dried.

**Groundnut or bog potato (*Apios americana*).** Sweet and starchy, these small tubers contain about 17 percent crude protein and are therefore among the most nutrient rich of all the New World tubers, more so even than the potato. They can be eaten raw or prepared like potatoes, or added to soups and stews like beans or peas. There is considerable breeding being undertaken to develop commercially feasible crops, with over ten named cultivars in circulation among experimental growers at the present time. The commercial advantage of this tuber is that it can be grown on marginal land and it is not subject to a large number of pests.

**Jerusalem artichoke (*Helianthus tuberosus*).** First noted by Europeans about 1605, the Jerusalem artichoke

has experienced numerous cycles in popularity over the ensuing centuries. It was promoted by French agricultural writers Antoine Parmentier (1789) and especially by Victor Yvert (1790) who wrote a treatise on the subject, and is even mentioned by American cookbook author Amelia Simmons in 1796. Rich in inulin, the Jerusalem artichoke was widely cultivated by native peoples in North America, especially in the Midwest where it is thought to have originated.

There are five basic tuber types and a wide range of skin colors, from pure white, to red, purple, even brown. There are also discernible differences in flavor, but nearly all of the known varieties share in common a strong resemblance to the flavor of cooked artichokes, hence the name: artichoke of New Jerusalem. Most native peoples referred to the plant as a “sun root,” which is botanically more correct. The Jerusalem artichoke has been hybridized with the sunflower to yield the Sunchoke, which is high in sugar and may eventually serve as a commercial source for sugar.

A number of Jerusalem artichoke cultivars are considered improvements over the knobby, hard to pare wild sorts. These include Challenger, French Mammoth, Skorospelka (developed in Russia), Stampede (developed by Ontario Indians), and Fuseau, a tapered sort resembling a sweet potato in shape which was developed in Egypt about 1913.

**Maximilian’s sunflower (*Helianthus maximilianii*).** This is a near relative of the Jerusalem artichoke, which produces tubers or thick tuberous roots prepared and eaten in the same manner. It is native to the dry prairies of the Great Plains, where it was first identified by Prince Maximilian of Wied-Neuwied during a trip up the Missouri River between 1815 and 1817.

**Water parsley (*Oenanthe sarmentosa*).** An aquatic tuber with black skin and starchy white flesh tasting of parsley. It was highly esteemed by the native peoples of the Pacific Northwest.

**Wild potato (*Solanum fendleri* and *Solanum jamesii*).** These are small, marble-size potatoes found in the Southwest. They were gathered mostly by the Navajo, Hopi, and other native groups. The Fendler Wild Potato is said to taste like a chestnut when cooked. The Colorado Wild Potato (*Solanum jamesii*) was eaten raw, baked or boiled and can be stored for long periods of time. It was also dried and ground to make flour. Both species contain bitter toxins that can be neutralized when cooked with an alkaline substance.

**Wild sweet potato (*Ipomoea pandurata*).** This is in most ways similar to the Bush Morning Glory, except that it has a vining habit and grows in the eastern regions of North America rather than on the Great Plains. It was considered an important food source by Eastern Woodlands peoples.

**Wood sunflower (*Helianthus strumosus*).** A near relative of the Jerusalem artichoke, the tubers are less well formed, more elongated and knobby. The flavor is similar to a Jerusalem artichoke. The plant grows in forest clearings in eastern North America and has become relatively rare. It is cultivated on a very limited basis by specialists interested in heirloom crops.

### South America (Including Central America and Mexico)

This region of the world possesses the richest natural diversity of tuberous species, yet nowhere is the literature more confusing than from this continent. As the late Sophie Coe pointed out “the treachery of common names” can transform comparative research into linguistic nightmares, especially when it comes to cookery. Local names for plants change not only across national borders, but from one region to the next, and even among neighboring native languages. All of these aliases show up in regional cookbooks, which must be read with great care. The *ocumo* of Venezuela is the *malanga* of Puerto Rico and the *quequisque* of Nicaragua. Not all of the multitudes of local names are listed below, just those that are most commonly mentioned in culinary literature. Nor are all of the South American tubers included, since many of the minor ones like swamp lily (*Thalia geniculata*) are consumed primarily or exclusively by indigenous ethnic groups. The tubers included here are those that play an important role in agriculture and kitchen gardens, and many of them are now commonly grown in other parts of the world.

**Arrowroot (*Maranta arundinacea*).** Some botanists refer to the root of this plant as a tuber when it is round and as a rhizome when it is long, even though the genetic material is identical. This difference in shape is owing to physical changes as the plant matures, but for the purposes of cookery, it is treated here as a tuber. This is a plant that grows on boggy ground or along streams, and in the West Indies where it originates, it was grated, boiled, or baked in the manner of a potato by the native peoples. Because it is so rich in starch, arrowroot became an article of trade by the eighteenth century, the starch being an ideal thickener in sauces as well as a basis for soupy gruels in invalid cookery. It also became one of the base thickeners for *budín*, and a key ingredient in delicate *galletas*. Arrowroot is now grown mainly as a source of culinary starch, but its culture has spread to several parts of the world. In Asia, it is planted along the borders of rice fields, so it is an important secondary crop for small-scale farming. It is also employed in the manufacture of noodles.

**Cassava (*Manihot esculenta*).** Also called manioc and yuca, cassava has become one of the most important food crops in the tropics, particularly in sub-Saharan Africa. The nutrient-rich leaves are boiled like spinach, the tuber cooked like potatoes, and the starch used for making tapioca. The genetic origin of the plant is tropical South

America, most likely northeastern Brazil. It was brought under cultivation about 3,000 B.C.E., but had spread to many areas of Central America, Mexico, and the Caribbean by the time Columbus first saw it in 1492. It became an important military ration for the conquistadors because it could be stored for a long period of time. Since the 1500s, cassava has been introduced and thoroughly integrated into the agricultures of Asia and Africa. In South America entire cookbooks, such as Enrique Tercero Hoyos's *Casabe* (Bogotá, 1996), are devoted to the preparation of this vegetable. A more complete discussion of cassava and its complex history are provided in a separate article.

**Cush-cush or Indian yam (*Dioscorea trifida*).** Also called Mapuey. Compared with the more popular yams introduced from the Old World, this may be considered a minor crop limited to the northern coast of South America, parts of Central America, and the Caribbean. It has not received much attention in scientific literature, although it is the only New World yam raised for food. In Afro-Caribbean cookery, it is treated like the sweet potato and is superior in quality. The texture is very fine and creamy when mashed. There are several landraces, most with white flesh, others with rose or purple flesh.

**Dahlia (*Dahlia pinnata*).** The common garden dahlia now grown as an ornamental was not noticed by European horticulturists until it was sent to Spain in 1787. Prior to that, its tubers were cultivated or gathered from the wild by the native peoples of southwest Mexico. The dahlia is still considered one of the native ingredients in the cookery of Oaxaca, and the petals make a colorful addition to salads. Today, there are several cultivars raised especially for their large, sweet potato-like tubers. There the similarity stops, since these tubers do not cook soft, but rather retain a certain celery-like crispness that is ideal for vegetable stir-fries. The flavor is complex, something akin to steamed pumpkin with overtones of sunflower seeds and a hint of spinach. Dacopa, an intensely sweet extract from the tubers, is used to flavor beverages in Central America. This extract tastes like strong mocha.

**Madeira vine (*Androdera cordifolia*).** This fine ornamental vine, which was a popular verandah plant in Victorian America, is actually a very good garden vegetable with many overlooked qualities. Its succulent, fleshy leaves may be eaten raw or cooked, and its white, nutty tubers make excellent additions to a meal, especially because they retain their crispness if not cooked too long. Otherwise, when cooked soft, they resemble potatoes. This is a relative of Malabar spinach and ulluco, which is still commonly found in Central American markets. It originates in the tropical parts of South America, but outside the western hemisphere it is not widely dispersed as a food plant except for a few places in Asia, such as Japan and the Philippines.

**Malanga (*Xanthosoma sp.*).** Christopher Columbus encountered this plant during his voyages to the New

World but no one yet has established a universally accepted name. It was called *taia* in Carib, but goes by *yautia* or *malanga* in Spanish, *ocumo* in Venezuela, *chou caraibe* in the French West Indies, *tannia* and *calaloo* in the English-speaking islands, and *quequisque* in Nicaragua. The confusion is even greater since these names refer to specific species in some localities, while in others they are just general monikers to differentiate the plant from taro, which it resembles. The *yautia amarilla* of the Dominican Republic is *Xanthosoma atrovirens* and not any other yellow-tubered species, while the *yautia morada* of Puerto Rico is the same species as Nicaraguan *quequisque* (*Xanthosoma violaceum*). To get it right in the marketplace, it is almost necessary to bring a botanist along. Confusion arises from the fact that within each species there are numerous varieties and indeed many named cultivars. To the subsistence farmers of the Caribbean and South American tropics where this plant originates, all of this does not matter; it is only how it tastes that counts.

The most commonly grown species is the white tubered sort called *yautia blanca* or *malanga blanca* (*Xanthosoma sagittifolium*), a key ingredient in Cuban and Puerto Rican cookery. The differences between malanga and taro are very noticeable when subjected to comparative taste-testing. The malanga is finer textured, easier to digest, and contains more starch. The leaves, which are cooked like greens, are also richer in protein and minerals, and the Haitians believe they taste a bit like mild cabbage. The underground parts harvested are the lateral tubers, which means that by digging beside the plant, it is possible to remove tubers as needed without killing it. This low maintenance, perennial food supply is one reason that the vegetable is so popular among the rural poor in the tropics. It also grows in areas with less rainfall than required by taro and will even grow in well-drained uplands. For this reason, its cultivation has also spread to Hawaii, Malaysia, the Philippines, Indonesia, and much of Southeast Asia, where it is used like taro.

**Mashua (*Tropaeolum tuberosum*).** Also known as Año, this species of the garden nasturtium has been cultivated since ancient times in the Andes and has no known ancestral forms. It grows like a typical vining nasturtium and produces red and yellow flowers during the summer, but requires day lengths of twelve to nine hours for tuberization. The tubers are cone-shaped and thickened toward the bottom. There are two distinct varieties, a white skinned tuber flushed with violet, and a red-speckled one with pale yellow skin. Both are cooked before they are eaten and taste much like Jerusalem artichokes. Like oca and ulluco, the plants are highly productive and easy to harvest. Historically, Inca generals shipped large quantities of the tuber along with their armies under the belief that it would suppress venery so that the soldiers would forget their wives and devote themselves more energetically to fighting. It does not seem to have this effect on the Spanish.

**Oca (*Oxalis tuberosa*).** Next to potatoes, oca was—and still remains—one of the most important tubers raised in the high Andes. It forms an historical triumvirate with the potato and ulluco, and speaks for the genius of the farmers who figured out how to coax prolific tuberization from plants that in the wild would never have supported the complex societies that later evolved in that part of the world. In fact, oca has been cultivated for so long that the ancestral plant is now lost.

Oca is rather hardy, with fleshy leaves and stems, and a multitude of colorful tubers that form very late in the season, when the days grow exceptionally short. In the Northern Hemisphere, this means that oca will not tuberize until late November; therefore, it must be grown in cold frames, polytunnels, or cool greenhouses in order to produce a crop. This is not a problem in the oca-growing regions of the Andes, where frosts come late, but it has hindered the spread of oca to other parts of the world. The French and English, for example, experimented with oca in the 1820s, but it remained a curiosity, more ornamental than culinary.

Ocas are sold by color in Andean markets, and there seem to be at least 60 variant forms, from snowy whites to bright, waxy reds, even black. In spite of this biodiversity, which certainly excites the eyes of experimental chefs, ocas are essentially of two sorts: the sweet ones that are eaten raw or sun-dried like figs to make *caui*; or the bitter ones that are boiled, and boiled again, then freeze-dried to make *ckaya*. Dried ocas are more nutritionally rich than freeze-dried potatoes (*chuño*), and therefore form an important supplement to the Andean diet. Fresh ocas resemble miniature potatoes, even to the “eyes,” which can be planted like potato eyes in the early spring. Europeans find them bland-tasting, but when added to soups or raw to salads, they greatly enhance the visual appeal of the dish. Furthermore, the Indians of the Andes consider oca a potent aphrodisiac, so there may be unsung benefits to promoting oca beyond its old native borders.

**Potato (*Solanum tuberosum*).** Known as papas in Quechua and in Spanish, potatoes have been cultivated in the Andes roughly since 3700 B.C.E. (there are scholars who argue for an even older date of domestication). Seven distinct species of potato are still cultivated in South America, although only *Solanum tuberosum* is presently grown worldwide. The long tubered species *Solanum ajanhuiri* was introduced to France from Peru about 1815. It is still cultivated by potato connoisseurs, especially the black variety called *Negresse* or *Truffe de Chine*, which has become popular with Parisian chefs because of its truffle-like flavor. A detailed discussion of the potato and its history and near relatives may be found in a separate article.

**Sweet potato (*Ipomoea batatas*).** This tuber was brought under cultivation along the western coast of South America about 2800 B.C.E. It spread to nearly all

parts of South and Central America, but never reached Mexico proper. The early Spanish likened its flavor to marzipan, and it was this potato, not the Peruvian potato, that was first sent to Europe. Sweet potatoes were grouped into two basic types by indigenous peoples: a mealy, starchy type used for bread making, and the fine-grained sweet types known today. Since the Spanish preferred only the sweet types, the starchy types have become extinct, except for a small pocket of “relic” cultivars found in parts of the Pacific and among the Maori of New Zealand.

The history of the sweet potato is complex, for it is one of the few New World plants that spread beyond the hemisphere prior to European contact. For a fuller treatment of the sweet potato, refer to the article by that name.

**Ulluco (*Ullucus tuberosa*).** A relative of the tropical Malabar spinach, ulluco prefers growing conditions quite the opposite: short day length, high humidity, cool weather, ample rainfall. In the high Andes it has been interplanted with potatoes for thousands of years and is still grown in a region stretching from Bogotá, Colombia, into northern Argentina. It is one of the most frost-resistant of all the Andean tubers. Its native names are many, including *lisas*, *papa lisas*, *chuguas*, *rubra*, *timbos*, and *melloca*. The smooth-skinned tubers resemble miniature potatoes and are quite startling visually, coming in a rich array of yellows, purples or magentas, vibrant greens, and varieties that are speckled. There are six named cultivars which vary in sweetness or starch content. Some find the tubers bland when boiled, but when boiled and then fried, they taste like potatoes. They are also eaten raw with vinegar or dried in the sun to make *lingli*, an Andean snack food.

**Yacon (*Smallanthus sonchifolius*).** A near relative of the sunflower, yacon (pronounced ha-KON) has been cultivated in the Andes for almost 2,000 years and perhaps much longer. The name is a Spanish combination of Quechua *yacu* and *unu*, both of which mean water in the language of the Incas. This refers to the fact that the tubers are juicy like apples and will yield a pleasant beverage when pressed. This juice is also cooked down until thick to make a type of molasses called *chancaca*. The plant itself is a handsome ornamental, with large palmate leaves resembling tithonia. The leaves are used in medicinal teas and are considered antidiabetic. The long, smooth, sweet-tasting tubers were treated as fruit by all Andean peoples and are still sold among fruits in the country markets of Peru, Bolivia, and Ecuador.

Images of yacon tubers and leaves dating from 500 C.E. have been found on cloth fragments at Nazca in Peru, direct evidence that the plant was already considered an important food source. Genetic evidence of long cultivation is also evident, since many strains have been reproduced from cuttings for such a long time that the flowers have become infertile. It is known from early Spanish accounts that yacon was mostly planted along the

margins of fields and that its cultivation was spread over a wide area of the Andes by the Incas in the period immediately preceding Spanish conquest. Because yacon is day-length sensitive, many species cannot be grown outside their native habitats. There is some effort at present to breed out this sensitivity so that yacon can be grown more easily in North America and Europe. Since yacon's sugars can be tolerated by diabetics and it is nutritionally very low in calories, the plant offers a number of interesting possibilities for further development.

Aside from the yacon discussed here, there are at least 20 other species of yacon found in Mexico, Central and South America. Only a few of these have been brought under cultivation, although several types were treated as "managed" plants by native peoples. That is, they were maintained in the wild rather than cultivated in fields. Many of the Central American yacons produce edible seeds that resemble small, black sunflower seeds. They make excellent bird feed and would probably appeal to humans if they could be bred to grow larger. The seed also yields an oil which is highly valued for its medical properties.

***Yam bean (Pachyrhizus erosus).*** Also known as *abipa*, *xiquima*, and *jicama*, this is often described as a mono-tuberous root rather than a true tuber. Native peoples treated it as a tuber, and the Mayans included it in many of their food riddles, mentioning both yellow and white sorts. The plant is indeed a bean with a highly ornamental vine, but the beans themselves are toxic and narcotic. Only the tuber is eaten, and generally, if we are to judge by Aztec codices and early Spanish accounts, this meant eaten raw for its refreshing crispness.

The plant is native to tropical America, although its center of biodiversity appears to be Central America where other species are commonly found. The archaeological record has not been helpful, but it is likely that the yam bean was domesticated in that part of the New World first, and then spread to other cultures. It was exported to the Philippines by the Spanish, and from there

spread to other parts of Asia during the 1600s. It is now also grown in East Africa, where it has become quite common, although it is generally cooked.

It is also being marketed in the United States and Europe under the Mexican name *jicama* and plays an important role in Mexican and Central American cookery to this day.

### **AFRICAN AMERICAN FOODWAYS**

A discussion of African American food must include the cultural patterns associated with how, where, when, with whom, and why certain foods are consumed and the patterns of food procurement, preparation, presentation, and dispensation. Studies of food as part of a cultural system should consider dietary behavior, the environmental conditions in which foods are grown, the meanings associated with food, the social structure and material culture affecting food, and the historical factors that contribute to the persistence or change in food behavior. Food meets a host of human needs—political, economic, communal, cognitive, and affective as well as nutritional—and it has a role in power relations, stereotypes, and assumptions.

Before discussing African American foodways, it is important to first clarify what is meant by the term “African American.” *Webster’s Encyclopedic Unabridged Dictionary of the English Language* (1996) defines “African American” as “a black American of African descent.” This discussion narrows that definition to focus on black persons of African ancestry whose lineal relatives (parents, grandparents, great grandparents) have resided in the United States for several generations. The focus on lineal relatives for establishing African American foodways is based on the assumption that most children grow up

in households with adult lineal relatives (parents and grandparents) and/or with adult collateral relatives (aunts, uncles, cousins), who in turn grew up in households with their lineal and/or collateral relatives. Where adults in the household grew up is important because they influence the initial foodways of children. Black parents who grew up in Africa or the Caribbean pass on preferences for foods from those cultural areas that are different from the preferences of black parents who grew up in the United States. Parents and close relatives also pass on many of the cultural patterns that surround dietary content. For the purposes of this discussion “foodways” are products of multigenerational historical process, reproduction, and change.

### **Soul Food: A Metaphor of Group Identity**

Linda Keller Brown and Kay Mussell, in *Ethnic and Regional Foodways in the United States: The Performance of Group Identity* (1984), discussed foodways as a metaphor of group identity and included contributions on Jewish Americans, Italian Americans, Russian Americans, Mexican Americans, Cajun Americans, Hindu Americans, and Florida Seminole Indians. However, no contribution focused on African American foodways even though during the 1960s soul food was adopted by millions of African Americans as a marker of ethnic identity, and soul food restaurants emerged wherever significant numbers of African Americans resided.

The concept of soul food emphasizes both content and preparation styles. Whitehead commented:

Pork is a favorite soul food meat that must be fixed in a certain way. In addition, soul food requires the use of pork fat (“fat back,” salt pork, streak-o-lean) as a seasoning in the cooking of vegetables in a slow stewing manner (vegetables such as collard and turnip greens, black-eyed and field peas, green and lima beans), and in the frying of other favorite foods such as chicken, fish, and [white] potatoes. (1992, p. 28)

William Wiggins has written that soul food restaurants include:

down-home breads (cornbread, cracklin’ bread, and biscuits), vegetables (collard, turnip, and mustard greens, candied yams, black-eyed peas, red beans and

rice, fried okra, fried green tomatoes, green beans, pigeon peas, and squash), meats (fried chicken, shrimp, oysters, white buffalo, and catfish, neckbones, chitterlings, ham, gumbo, burgoo, and barbecue), and desserts (apple, peach, and cherry cobblers, sweet potato, transparent, pecan and apple pies). (1987, p. 81)

Some African Americans include rice on the soul food menu. Delilah Blanks (1984) found older African Americans in the South added wild animals, such as squirrels, rabbits, opossums, and deer. Flour-based gravies are a favorite with meats and rice. According to Wiggins, slaves began New Year's Day festivities as early as 27 or 28 December for ample celebration. They ate hoppin' John and attended watch night services to ward off family separations in the new year (Wiggins, 1987, p. 26). Many African Americans still eat hoppin' John or rice and black-eyed peas on New Year's Day for good luck in the upcoming year.

Among the soul food preparation styles are foods high in fat, salt, and sugar. Meats and other foods are fried, and most vegetables are stewed with pork fat. Whitehead reports that while dining with one of his study families in eastern North Carolina, at a single meal he was served fish, slices of country ham, corn bread, and white potatoes fried in pork fat and green vegetables stewed with salt pork as a seasoning. Country ham, preserved in a heavily salted brine, is a salt-laden favorite in the soul food menu (Whitehead, 1992, p. 98). Soul food is also spiced with red pepper (cayenne), malegueta peppers, hot pepper sauces, mace, allspice, cinnamon, cloves, sesame seed (benne), filé powder from sassafras leaves, thyme, and vinegar.

First-time patrons at soul food restaurants often find the drinks and desserts overly sweet. Heavily sweetened iced tea is the traditional drink, but unsweetened tea is often available. Whitehead observed that iced tea, lemonade, and Kool Aid, made with one cup of sugar to seven cups of water, were the favorite summer drinks of his study households. Fat (butter) and sugar are also used liberally in the preparation of favorite side dishes, such as candied "yams," a sweet potato dish, and desserts, such as apple or peach cobblers or pies; sweet potato pie and pudding; banana pudding; and chocolate, pineapple, coconut, lemon, and pound (plain) cakes.

With the increased awareness of heart disease, stroke, and diabetes, many African Americans have felt the need to reduce their consumption and preparation of these traditional soul foods, though they have not found it easy to change. Studies indicate that canned greens, frozen fried chicken, macaroni and cheese, corn or bread pudding, and sweetened tea are high in cholesterol, sodium, and saturated fat. Consequently public health agencies like the National Cancer Institute and cookbooks like *The New Soul Food Cook Book* (1996) by Wilbert Jones suggest ways to maintain flavors and diminish unhealthy habits.

### The Southern Flavor of African American Culture and Foodways

The emergence of soul food was part of a cultural revitalization resulting from the black identity sentiments many blacks expressed in the 1960s. Most revitalization movements initiated by people of African ancestry in the Western Hemisphere, such as the Rastafarians of Jamaica, the Black Muslims in the United States, and Kwanzaa participants, seek to revive African cultural trends.

Evidence also suggests that various components of African American foodways have their origins in Africa. For example, the soul foods black-eyed peas, collard greens, okra, and benne or sesame seeds probably came from Africa. Archaeological discoveries indicate that "the meals the black women prepared for themselves and their families . . . readily could have used techniques and ingredients important in West African cookery" (Yentsch, 1994, p. 196). Anne Elizabeth Yentsch admits, however, that raising the point of African origins opens a Pandora's box because determining origins is "complex and tricky." The predominant cultural source of African American foodways is not Africa but the American South, involving a multiple-generation creolization process with contributions from Europeans and Native Americans as well as from Africans.

Pork and chicken are the dominant soul food meats, derived from animals the Europeans brought to the Americas. The Europeans, as maritime and colonial powers, were responsible for the movement of foods from continent to continent. For example, Europeans brought sugar cane to the Americas and thus contributed to the sweet foods in southern and soul food menus. Europeans brought foods from the Caribbean and Central and South America, "sometimes by circuitous routes through Europe and Africa and Asia," that became part of the southern and soul food diet, including "hot and sweet peppers, peanuts, tomatoes, lima beans, white potatoes, and sweet potatoes," chocolate, pineapples, lemons, and coconuts. (Egerton, 1987, p. 13). Europeans also brought rice to the lowlands of South Carolina and Georgia, from where it spread to Louisiana and Arkansas (Egerton, 1987, p. 307).

These foods Europeans brought to the American South became inextricably linked to the enslavement of Africans. For example, the slaves ate yams, peanuts, corn, and rice during the middle passage. Citrus fruits, like limes and lemons, hot malegueta peppers, herbs, and spices were provisioned during the middle passage for medicinal purposes. West African or Gold Coast slaves, who had centuries of experience, cultivated rice in the lowlands of South Carolina and Georgia (Egerton, 1987). Sugar cane traveled the circuitous route "North Africa to Spain and Portugal with the Moors; from Portugal to Madeira with the Portuguese; from Madeira to the Canary Islands with the Spaniards; and from the Canary Islands to Santo Domingo with Columbus . . . [and finally] to Louisiana in 1751" with the Atlantic slave trade (Mintz,

An upper-class African American family eating dinner in their home during the early 1900s. COURTESY OF THE LIBRARY OF CONGRESS.

1991, pp. 117–126). The Atlantic slave trade also introduced West African yams, which were replaced by sweet potatoes, millet, sorghum, rice, plantains, bananas, corn, cassavas, and palm oil.

Native Americans contributed maize or corn; a variety of peas and beans; fish, such as catfish and trout; and seafood, such as herring and shrimp, to southern diets. Indians taught white southern colonists and black slaves to hunt wild animals, such as opossums, deer, rabbits, and squirrels, which were still soul food items in the 1980s. Slaves quickly adopted bird hunting from Native Americans. European travelers' accounts noted that guinea fowl and other birds were a source of meat in West Africa. African Americans in the low country and Virginia were particularly shrewd "chicken merchants" (Yentsch, 1994, p. 203; Morgan, 1998, p. 367).

Archeological evidence suggests that African and Native American cultures were intertwined primarily in methods of consumption and in preparation of foods like rice and corn. During the colonial period, African meals consisted of a starchy main course accompanied by vegetables and a small serving of meat. Customarily the food was prepared in a large container and was eaten with hands or spoons (Ferguson, 1992, p. 97 *n*). Gourds were used as eating utensils and musical instruments. Leland Ferguson noted that the shards of cooking pots suggest commonalities among the foodways of Africans from several countries and Native Americans. Europeans influenced African and Native American food-related material culture, most notably in the adoption of such items as iron pots and wooden buckets. But Ferguson and others suggest that the manner of their use was adapted to African familiarity.

Given the contributions of Europeans and Native Americans, whites and Native Americans with cultural roots in the South could just as well view soul food as their own. Yet African contributions to southern foodways were considerable, as for centuries Africans and African Americans dominated the food scene through the

preparation of these foods and thereby claimed the tradition. During the antebellum period, the slave cook was the primary food preparer for both the white plantation owner and the black slave families. For slaves

the kitchen was one of the few places where their imagination and skill could have free rein and full expression, and there they often excelled . . . one of the few places where either blacks or women could let their guard down and be themselves. Almost everywhere else, they had to conform to binding roles that stifled expression and killed creativity; but in the kitchen, they could be extravagant, artistic, whimsical, assertive, even sensuous . . . herein may lie the ultimate explanation for the natural superiority of Southern food. (Egerton, 1987, pp. 15, 17)

In its "natural superiority," southern food tends to be more spicy than foods from other regions of the United States. The slave cooks took advantage of the spices that came into North America from Africa, the Caribbean, and Central and South America. These spices not only stimulated the taste buds of the planter class but also made the lowly food items given to the slaves, such as the excess fat, snouts, tails, ears, and intestines of the pig and the bland and sometimes bitter greens, more tasty.

Of course the majority of African Americans with cultural roots in the South do not eat the same foods or prepare them the same way their ancestors did. However, the South has historically had the largest presence of African Americans. Even with the mass migration of blacks to the urban centers of the North and West during the first three-quarters of the twentieth century, the percentage of African Americans who remained in the South never dropped below 50 percent. As economic and political opportunities in the South improved, there came a reverse migration: a large number of African Americans returned, and by 2000 the South recorded a higher increase in African American population than in any other region in the United States. Consequently there has been a continual evolution of an African American culture in the South that includes African American foodways.

Even for the blacks who migrated out, the South retained its important cultural influence as ties continued with family members "back home," through holiday visits, attendance at church revivals and homecomings, and shared network functioning such as child and parental care (Stack, 1974). Migrants returned to get some of that "old down home cooking." Moreover, when African Americans moved to urban areas of the North and West, they took their food traditions with them along with their religions, which tended to perpetuate their foodways (Whitehead, 1992).

The foregoing should not be read as an argument for a synchronic view of southern or African American foodways—that is, one that ignores historical antecedents. Neither system has endured unchanged. Certain foods are consumed in all regions of the country and

by members of most if not all ethnic groups. Consequently some argue that a truly “southern” diet and a truly African American diet do not exist (Fitzgerald, 1979). The notion that American food habits and preferences are national is based on supermarket and fast-food chains, mass media marketing, and the spread of ethnic groups and their traditional food preferences to all regions of the country. For example, Italian pastas, particularly spaghetti, and pizza have long been eaten in all regions, and Mexican and Chinese foods have become American favorites (Gabaccia, 1998).

### **A Cultural Ecological Approach to Foods and Foodways**

The argument against specific southern and African American foodways parallels the argument that a southern culture does not exist because nationwide communication and transportation networks have incorporated southern components into a national, multiethnic American culture. However, these arguments focus narrowly on what people eat rather than on foodways as part of a larger biocultural system or what many foodways scholars refer to as a cultural ecological approach (Jerome et al., 1980). In this approach, the question is not to what extent other American foodways have permeated southern or African American food habits but rather to what extent southern and African American foodways have permeated the food habits of other Americans.

Thomas R. Ford described culture as a “historical production of environmental adaptation” (1977, p. 4). With regard to the study of food and foodways, five theoretical principles might be considered in a cultural ecological approach.

- (1) Culture is a process of historical reproduction, and foodways as part of a cultural system are reproduced from generation to generation.
- (2) Food is necessary for biological survival, thus the nutritional status of an individual or population is related to the availability and accessibility of food.
- (3) The availability and accessibility of food is not only a function of the nutritional capacity of the physical environment but also a function of social and cultural influences.
- (4) Social and cultural adaptations are made to factors related to the availability and accessibility of food.
- (5) The persistence of factors related to the availability and accessibility of food contributes to the continuity of social and cultural adaptations developed in response to such factors.

### **The Historical Foundation of the African American Traditional Core Diet**

The cultural roots of African Americans in the South were firmly established during more than two hundred years of slavery. Because slavery was a “total institution,”

### **TASTE PREFERENCES FOR FATS AND SWEETS: THE U.S. SOUTH VERSUS THE FRENCH**

Tony Whitehead spent the 1987–1988 academic year working with the noted French nutritional anthropologist Igor de Garine. Before Whitehead left for France, the owner of Dip’s Country Kitchen, a soul food restaurant in Chapel Hill, North Carolina, implored him, “During your research in France, would you find out for me why is it that the French love fat foods and sweets as much as we [black people] do, but they don’t seem to get as fat we do?” While Whitehead did not have the means to empirically explore this question, from his observations he concluded that fat, in particular butter and cream, was quite present in the French diet and preparation styles and that the French loved desserts. However, their desserts and drinks did not taste as sweet as the ones he was familiar with as a native and food researcher in the American South. And the French did not snack frequently on sweets, which were relegated to specific times of the day, the afternoon, equivalent to the English tea, and the evening. The French would just as likely have cheese for dessert. Even though the French have multiple courses at meals, they eat small quantities of each course. Finally, eating for the French seems to be a social event, with much talking and social interaction with wine, rather than an eating event.

it influenced the availability and accessibility of food and slaves’ responses to these conditions (Stampp, 1956). Most of the foods available to slaves were passed on to them by their owners. African Americans in the South in the twenty-first century use preparation styles similar to those developed by slaves.

Plantation records, slave narratives, and archaeological examinations of slave quarters provide information on the diets of both blacks and whites. The planter class in the South consumed the “better” parts of hogs, chickens, and cattle; fresh milk; butter; and cheese. They passed to slaves the feet, necks, ears, and tails of hogs; hog chitterlings, kidneys, livers, and brains; chicken feet, livers, and gizzards; and buttermilk. Slaves were frequently allotted cornmeal, salt, pork, molasses, and her- ring, as these foods could be stored in bulk by the planters (Gibbs et al., 1980).

Many planters encouraged slaves to cultivate gardens for their own subsistence (Singleton, 1999, pp. 20–21). However, the foods slaves were allowed to produce for

themselves varied. On some plantations slaves raised chickens and ducks and grew cabbage, collard and turnip greens, white potatoes, sweet potatoes, and a variety of beans and peas. Other planters prohibited slaves from producing such foods in fear that the slaves would sell them to earn money to buy their freedom or trade them for whiskey (Gibbs et al., 1980). According to Todd Lee Savitt (1975), planters often used slave produce to pay certain debts, and the slaves were allowed to keep the remaining produce for themselves.

Frequently slaves had to supplement their diets by gathering plants and wild berries; hunting small game, such as squirrels, rabbits, opossums, and raccoons; fishing; and stealing. Some scholars have placed these methods of food procurement within the context of plantation power dynamics and resistance, arguing that slaves in some instances exercised a modicum of autonomy by resisting planter attempts to control their diets. Fishing, hunting, and gathering gave slaves some sense of autonomy, but true acts of resistance involved theft of livestock and other foodstuffs, such as smoked meats, eggs, chickens, and vegetables (Yentsch, 1994).

Many of these food items are included in the African American traditional core diet that was characterized by Whitehead (1992) and Delilah Blanks (1984). In separate studies in North Carolina in the 1970s and 1980s, Whitehead and Blanks found that most were still regularly eaten in African American households. Presumably this traditional core diet has persisted over a number of generations.

Whitehead and Blanks found that other foods in the core diets of their study families were not a regular part of slave diets according to historical accounts. Among these foods are pork products, such as hams, ribs, chops, loins, and shoulders; whole chickens and chicken breasts, thighs, legs, and wings; beef products, such as ground beef, roasts, and steaks; fresh fruit; desserts, such as fruit pies, cobblers, cakes, and cookies; and beverages, such as sweet milk, coffee, tea, and lemonade. This does not mean that some slaves and some black free persons did not eat such foods, but according to historical accounts most African Americans did not eat them frequently during the slave period. It is likely that after emancipation more African Americans raised their own food and traded for or bought a wider variety of foods.

African Americans consumed other foods added to their diets by the twentieth-century mass food delivery and marketing systems. Whereas many African American traditional core foods were fresh produce, most of the foods were processed, canned, prepackaged, or frozen. Whitehead's research was motivated by the high fat and low fiber content of traditional core foods, which public health professionals blamed for the higher incidence of heart disease, hypertension, stroke and other cardiovascular conditions, diabetes, and rectal and colon cancers among blacks and whites in the southeastern United States. However, in a study published in 1996, Barry M.

### AN EXPERIMENT TO TEST SOUTHERN PREFERENCE FOR SALT AND SUGAR

While Tony Whitehead's research in North Carolina was only exploratory, his findings were suggestive. Whitehead's original sample was the membership of 43 total households of 193 African Americans 10 years of age and above. A nutritionist on Whitehead's research team, Judith Katona Apte, created two simple instruments to explore sugar and salt preferences. The first was five water and sugar mixtures with the amount of water evenly calibrated between each. Mixture 1 had the least amount of sugar, and mixture 5 had the greatest. The second instrument was similar, consisting of broth-type mixtures with five different calibrated amounts of salt. These mixtures were first administered to ten graduate students at the University of North Carolina who were asked which mixture they preferred in their foods. Mixture 3 was selected by eight out of the ten students. The mixtures were then administered to the study participants. It was a methodological error to not pretest these instruments on research participants from the study community and adjust based on their preferred tastes. Nevertheless it was instructive that the most frequently stated preference of both salt (97 out of 141 cases) and sugar (111 out of 140 cases) concentrations was mixture 5. Even with the methodological error, the finding at least suggests that African Americans residing in this southern study community preferred higher concentrations of salt and sugar in their foods than did the ten graduate students, seven of whom were not originally from the southeastern United States. Whitehead observed that the favorite summer drinks among his study group had what might be considered higher concentrations of sugar (one cup) to water (seven cups) than what most Americans whose foodways are not southern would prefer. This also suggests that southerners and African Americans prefer foods higher in these ingredients.

Popkin and Anna Maria Siega-Riz found that between 1965 and 1991 many traditional foods like sweet potatoes, greens, and black-eyed peas had decreased significantly in the diets of poorer blacks. The study noted that, among all socioeconomic classes, consumption of fast-food items, including "pizza, tacos and pasta dishes loaded with hidden fats" increased (Popkin and Siega-Riz, 1996, p. 718). These foods contribute to the fact that proportionately more African Americans, especially women, are overweight than white Americans (Kumanyika, 1997).

## FOODS ACCESSIBLE TO SLAVES: THE AFRICAN AMERICAN TRADITIONAL CORE DIET

### Meats, Poultry, and Seafood

Pork Extremities  
 Chicken Extremities  
     wings, necks, backs, and feet  
 Chicken Organs  
     livers and gizzards  
 Wild Game  
     rabbits, squirrels, deer, and  
     opossums  
 Seafood  
     dried and salted herring; fresh-  
     water fish, such as trout, catfish,  
     kingfish, croaker, black and red  
     drum, and flounder; and shellfish,  
     such as crabs, clams, and mussels

### Vegetables, Legumes, Tubers, and Grains

Green Vegetables  
     okra; collard, mustard, and turnip  
     greens; poke salad, cabbages; and  
     pumpkins  
 Legumes  
     cowpeas and lima beans  
 Tubers  
     white potatoes, sweet potatoes,  
     onions, and turnips  
 Grains  
     rice, corn, and wheat  
 Wild Berries

### Breads, Sweets, and Beverages

Breads  
     cornbread and biscuits  
 Desserts  
     sweet breads made with  
     molasses or honey  
 Beverages  
     buttermilk and teas made from  
     roots and herbs, such as  
     sassafras

The African American participants in a study by Psyche Williams-Forson (2001) complained that the grocery stores in their communities did not provide enough variety in fish, fruits, vegetables (all items in the African American traditional core diet), and soy products. Rather, the perception of all African Americans preferring primarily pork and beef products and low dietary fiber foods still exists.

### Ecological Factors in the Post-emancipation Continuity of African American Traditional Core Foodways

The content of the African American traditional core diet became more entrenched after emancipation because the Civil War left the economy of the South devastated. Blacks and many whites resorted to the means of acquiring food that slaves and poor whites had learned during the slavery period, including gardening, hunting, fishing, gathering edibles, and for those who could afford it, raising chickens and pigs. However, lifestyle differences by race and class, including foodways, continued into the postslavery period.

Although slavery formally ended in 1864, the political economy of the plantation system did not. Sharecropping and tenant farming were the only forms of employment available to most blacks, and the economy maintained the marginal status of African Americans well into the twentieth century. African American foodways continued, particularly the modes of food acquisition. Gardening, hunting, and fishing remained significant forms of food procurement (Cussler and de Give, 1952). Blacks still got some food from “the white man,” but now

they had to pay cash or receive it on credit. For sharecroppers and small farmers, this frequently meant turning over a good portion of their pay from a good crop. The landlords who owned the farms allowed their tenants to garden and keep animals on these properties, similar to the pattern during slavery. Some foods and other goods could be purchased from stores in the nearest town or on the plantation, but usually with a credit line made out to the landlord. Thus workers saw little cash return for their labor as the landlords paid the accounts out of their wages.

Along with persistent poverty, the ecology of the region supported the continuity of the African American traditional core diet. The same foods grew wild or were cultivated, and African American families continued the food producing behaviors practiced during slavery with the exception of receiving rations from the planter (Gibbs et al., 1980). They raised many of the vegetables, legumes, and tubers they had consumed during slavery, and they continued to hunt and fish. Hogs and chickens were rather inexpensive to raise, partially because these animals ate pretty much anything the fertile area offered them.

These patterns of food acquisition continued in the twentieth century. Scholars of southern and African American foodways have noted that, although most foods were acquired from grocery and fast-food chains in the twentieth century, many African Americans in predominantly rural southern counties fished, hunted, and gardened; were involved in networks that killed hogs and shared pork products; and bought fresh produce from roadside stands and truck farmers who sold their produce in neighborhoods.

### SOUTHERN "HOSPITALITY" IN BLACK AND WHITE

John Egerton noted that the concept of "southern hospitality" grew out of a "grand style . . . of gracious and elegant living" that was made possible because of the "platoon of black cooks and servants" that made the "elegant service and distinctive cookery" associated with the social events of the higher southern (white) classes possible (1987, pp. 14–15). He commented that while "white mistresses may have had favorite recipes they prepared themselves . . . one of the most fascinating and ironic indicators of the pervasiveness of this social pattern was the spate of post-Civil War cookbooks aimed at white women who found themselves quite literally helpless after the Civil War" (1987, p.16). Mary Titus has suggested that the concept and its ideological attachments are rooted in a complex cultural legacy of conflict. Two of the primary indicators of hierarchy and markers of separation coded in southern hospitality as practiced by southern whites were table manners and etiquette books, which emerged out of a social institution shaped by racial complexities. Thus for southern whites this notion of southern hospitality was also practiced as a symbolic gesture or code demonstrating the social distance between cook and consumer. Yet while the white practice of southern hospitality was a code for the elegance (or superiority) of southern (white) cuisine, it was also complicated by the adoption of the idea of southern hospitality by black southerners. However, during his North Carolina research, Tony Whitehead observed that the southern hospitality practiced by African Americans was not about southern manners that southern whites used to construct some sense of false superiority. The southern hospitality practiced by African Americans maintained the frequent practice of inviting acquaintances to social events in which food is a primary component. Whitehead (1988) also found that those who accepted such invitations were incorporated subtly into the social network of the person doing the inviting. Certain obligations and rights are associated with such network inclusions, which may then be functionally operational during times of need or may simply lie dormant if no need arises.

#### Taste Preferences and the Continuity of Foodways

One of the primary contributors to the persistence of foodways, in particular food content and preparation styles, is human taste preferences and how they evolve over time. Preferences for fat, salt, and sugar are widespread in human societies, but in the United States,

especially in the South, the preferences for these ingredients are arguably the highest in the world. Methods of preserving and preparing foods have contributed greatly to taste preferences. For example, the preservation of pork in salt brine and the use of this salted pork and pork fat in the preparation of other meats and vegetables created a preference for salty, fatty foods.

Sweetened foods figure in the southern culinary tradition. Sugar was first brought to the West from the Orient, but it was only available to the well-to-do. Eventually sugar became the primary crop of West Indian plantations, production began in the American South, and sugar was available to the masses in colonial America. By that time the South had discovered other, less-expensive sweeteners, such as molasses; maple syrup, a technology borrowed from Native Americans; honey from bees brought by the Europeans; and sorghum syrup, also brought by the Europeans. Molasses was especially popular and was used in desserts, in drinks, and to flavor vegetable and meat dishes (Mintz, 1991, p. 125). Slaves worked in the sugar cane fields, where they sucked the cane and stole some for their own use. Sugar, a source of quick energy, may have contributed to the productivity of plantation labor, and fat and salt also may have been adapted for long hours of work in the hot fields.

Slave cooks influenced southern foodways and contributed to the southern preference for foods high in fat, salt, and sugar. Elizabeth Fox-Genovese commented:

The talents deployed in the kitchens owed much to the slave women's special way with herbs and spices and to recipes developed and handed down among themselves. They brought similar skills and even greater ingenuity to the preparation of foods for their own families and friends. Regularly resisting the masters' preference for communal kitchens, slaves pressed for raw rations that they could prepare for themselves. On some plantations, one woman would cook for all the slaves in a kitchen built specifically for the purpose, but even then, the last meal of the day usually was prepared individually in the family cabins. (1988, pp. 160–161)

Most of the foods passed on to the slaves, such as pig and chicken feet, necks, and livers; pig fat, ears, chitterlings, and brains; and chicken hearts and gizzards, may not be considered "food" by many Americans. However, the tastes the slave cooks created made them delicacies to many.

Slave cooks prepared food for their families and other slave families, and they also prepared much of the food for the families of their white owners. Most plantation owners had at least one female slave who prepared the family meals, and on large plantations even the overseer had a female slave who prepared his meals. Consequently slave cooks shared their taste preferences with the whites (Gibbs et al., 1980). However, the whites on the plantation ate ham, biscuits, relishes, and pies, while the slaves ate fatback, greens, and corn bread (Walter,

## ROMANTICIZING SOUTHERN FOODWAYS

Some years ago Tony Whitehead heard a nationally known journalist state humorously in a speech at the University of North Carolina at Chapel Hill, "The worst thing about the North is that there is nothing good to eat up there." Whitehead found the comment interesting because it was similar to many sentiments he had heard from a number of his study participants during his five years of food-related research in the area. Southerners think northerners "mess up" food. One study participant (SP) told Whitehead about being invited to a barbecue by a transplanted northern friend who was going to cook pork ribs on a gas grill. The SP told his friend the total purpose of cooking ribs was to cook them slowly over charcoal. His friend said such a procedure was too slow. The SP responded that you have to cook them slow so you can drink a lot of beer while they are cooking: "A barbecue is no good without drinking a lot of beer." The SP had to go further into the analogies and metaphors that characterize the speech narratives of many southerners to convince his friend to cook the ribs properly. He finally won his case with an analogy between food and sex:

The enjoyment of good food is similar to the enjoyment of good sex. You have a long period of foreplay to build your anticipation. This raises the actual act [eating or copulation] to the highest level of pleasure. Then afterwards, you fall into a nice pleasurable sleep—feeling very satisfied with the world and your place in it.

1971). The availability of slave cooks allowed white masters to entertain frequently, giving rise to the concept of "southern hospitality." Poor whites outside the plantation most likely adopted the preparation styles of slave cooks because they consumed the same less-desirable foods (Hilliard, 1972). These tastes for salt, fat, and sugar contributed to the notion of the "natural superiority of southern food" mentioned earlier.

The superiority of southern or African American foods over those of the North may not be an exaggerated romantic notion, however. In fact southern foodways have permeated the foodways of Americans in other regions of the country. The diffusion of southern preferences may be attributable to the human preference for foods made more tasty with fat, salt, and sugar and their availability to early American colonists in the North as well as in the South.

John Egerton pointed out that many mass food delivery systems, including the supermarket chains Winn-

Dixie and Piggly Wiggly and the fast-food outlet Krystal, originated in the South (1987, p. 39). These food delivery systems were successful in part because they responded to their clientele's taste preferences, including many items in the traditional African American core diet. Food outlets in other parts of the country emulated these pioneers in their high salt, high fat, and sweetened wares. Making foods more "tasty" makes them more attractive to consumers. While supermarket chains in other parts of the country did not initially stock popular southern items, such as pork fat, salt pork, ham hocks, and pig feet, eventually they discovered a market for those foods. Restaurants outside of the South added Creole and Cajun dishes and deep-fried catfish when they realized that southern tastes existed in their regions. Egerton stated, "Anyone who grew up on the [southern] food can attest, life without a little South in your mouth at least once in a while is a bland and dreary prospect" (1987, p. 49).

## Social Networks, Festive Occasions, and the Persistence of African American Foodways

Even as the foodways of African Americans changed with upward mobility, broader ethnic diversity in all regions

## JUNETEENTH

Juneteenth (19 June 1865) is one of the oldest-known celebrations to commemorate the end of enslavement. It is celebrated primarily in Texas as that was the day many enslaved Texans learned that they had been freed. Numerous tales attempt to explain the two-year delay between Abraham Lincoln's Executive Order of 1 January 1863 and the day the Texans heard the news. Many continue to make the annual pilgrimage to Galveston, the city where General Gordon Granger of the Union made the freedom announcement, to celebrate the day. While not as popular as Kwanzaa, Juneteenth is celebrated by African Americans throughout the United States with numerous cultural events. Because of its Texas roots, most menus for the event include barbecue spareribs or chicken. William Wiggins recorded that his first Juneteenth celebration included many foods familiar to African American southerners, "platters of barbecued chicken, long link sausages and brisket-sized chunks of beef, bowls of steaming brown beans seasoned with hunks of jowl bacon, a cold apple, lettuce, and mayonnaise salad, trays of white 'store-bought' bread, frosty pitchers of red lemonade, jugs of homemade blackberry wine, and a pan of peach cobbler" (1987, p. 3).

### MALE FOOD PREPARERS

Tony Whitehead found that, in most of the households in his study, meals and the food served at church suppers were prepared primarily by the females. However, he found that, particularly among African Americans, men often did take to the kitchen. This was particularly true for some special meal. One of type of food at both small and grand feasts is the pig barbecue, which in North Carolina is referred to as a "pig picking." When a pig picking is "done right," it is a ritual in which males are responsible for preparing and cooking the pig, which begins the night before the feast. Males kill and clean the pig so it can be placed on the hot grill at midnight. It is grilled through the night, and the host and other males apply the barbecue sauce. Through the night the men carry out other important male activities, such as gossiping, telling tall tales, and drinking. Whitehead reported that in the historically racially segregated county of his research, an African American pig picking was one of the few places where he saw black and white males socialize, probably because of the absence of white women. Shortly before the feast the host may cut up portions of the pig, or the guests may "pick" pieces from the well-cooked animal until nothing is left but the carcass, thus the name "pig picking." Through the pig picking males become noted for their "special" barbecue sauces and their abilities to season the pig. As guests eat the pig they also applaud the cooks' abilities and extol their reputations among the best barbecue chefs in the state. The pig picking can become a male competition when a number of noted barbecue chefs (whether anointed by self or by others) are invited to cook the pig and to bring their own sauces. They are given a portion of the pig, to which they apply their respective sauces. At the feast the guests are told which male was responsible for which portion, and they give their opinions about which was the best.

of the country, and greater concerns about health issues, the traditional core foods and foodways were preserved through festive occasions that bring members of a group together in celebration or recognition of some event of social significance. These occasions also reaffirm social ties crucial to the biological and psychological survival of the group and its members. This reaffirmation has been particularly crucial for African Americans. It was impossible for slaves to continue the social structures related to kinship, marriage, and family that they had known in Africa. However, slaves developed new social ties based

on family and kinship systems, churches, and voluntary organizations that survived into the twenty-first century.

Whitehead (1988) divided festive occasions into two types, impromptu and institutionalized. Impromptu occasions, such as a party or barbecue, are not related to any significant event. Institutionalized occasions are of three types, life cycle, calendrical, and communal, and correspond to three significant levels of social organization, the individual, the community, and the social network.

Life cycle occasions, such as births, initiations, weddings, and funerals, are celebrations of transitions or stages in the lives of individuals. Calendrical occasions are periodic celebrations recognized by the wider community, such as national holidays, like Independence Day, Memorial Day, Labor Day, or Presidents' Day, or annual religious events, like Easter, Christmas, and Thanksgiving Day. African Americans have created others, such as Kwanzaa and Juneteenth, which celebrates the termination of slavery. Communal occasions are celebrations of the social network, such as family reunions, church homecomings, and club or office celebrations.

Although life cycle occasions are celebrations of individual transitions, they are just as important for the network because they mark a change in status for both. For example, the network must adjust to the addition of a new member as a consequence of marriage or birth or to the loss of a member as a result of death. Similarly calendrical events are celebrated by the wider community, but networks take the opportunity to come together and reconfirm their ties. Food is central to festive occasions. In his North Carolina work (1992), Whitehead identified four types of African American food events: the meal, the petite feast, the small feast, and the grand feast.

Whitehead's study participants in a predominantly rural area defined a "meal" as a sit-down affair with others present. In other words, a meal is a communal occasion, not something one does alone. While meals are a day-to-day routine, the other three types of food events bring together household or network members into a festive occasion, and thus are referred to as "feasts." Feasts vary according to the number of network members present. A petite feast is best exemplified in the Sunday prechurch breakfast, which includes members of the household, and the Sunday postchurch dinner, which might include household and extended family members, the itinerant minister, and other guests. A small feast, such as a church or club dinner or an office picnic, includes network members from several local households. A grand feast, such as a family reunion or a church homecoming, includes extended network members, some from beyond the local setting.

In rural southern counties African Americans eat traditional core foods at evening meals. For morning breakfast and midday lunch some, particularly the young, take advantage of prepared and fast foods. These households usually have traditional core foods on certain days of the

week, such as for Friday or Saturday night dinner or for Sunday breakfasts, dinners, and suppers.

For African American families involved in church, Sunday breakfast and dinner are frequently petite feasts. The Sunday morning petit feast or big breakfast might be eggs; grits; sausage, bacon, country ham, fried chicken, or pork chops and rice smothered with gravy; and biscuits or rolls. The petite feast dinner, served after church at around 2:00 P.M., has similar foods in larger quantities with side dishes, such as macaroni and cheese and candied yams; drinks, such as lemonade, Kool Aid, and tea; and desserts, such as peach or apple cobbler or pie and pound, chocolate, pineapple, or coconut cake.

Traditional core foods are also served at small and grand feasts. Whitehead found that to be known as a “good cook” was important to the women of the church, who display their cooking skills at church dinners on Friday nights, Sunday afternoons, or Sunday evenings. Whitehead observed a functional aspect to the concept of “southern hospitality.” He suggested that a cook invites a new acquaintance to a food event, usually a petite or small feast, in part to broaden the affirmation of her or his status as a good cook.

African Americans raised in the South but living outside southern rural counties do not eat traditional core foods often, but many include them in feasts. African Americans with southern cultural roots gather on holidays for cookouts, picnics, or barbecues and share foods similar to those from home. In Washington, D.C., the staffs of representatives of some southern states have small feasts at which foods from their states are served. Sometimes a favorite restaurant from the home state caters the food, for example, North Carolina barbecue.

African Americans outside the South go “back home” on other holidays to have petite feasts with their relatives there, and they are expected to come home for family reunions and church homecomings. Family reunions usually last two or three days and involve several feasts. Subfamily units may hold petite or small feasts in addition to the grand feast or banquet dinner for all who attend the reunion. A church homecoming invites members who have moved away back for a celebration. Church members invite their ministers to their family reunions, but Whitehead found that some churches organized homecomings around the family reunions of several church members to broaden the occasion for those returning and to lessen concerns about making too many trips. Feasts are central to all of these occasions, and African American traditional core foods are the primary fare. Whitehead (1989) observed that the greatest incentive for traveling a long distance is to get one’s fill of that “good old down home cooking.” The more feasts during these visits, the better the time. Moreover, family members in the South know that food is an incentive and prepare enough so visitors can take a little back North with them.

Gulla basket for storing dried okra. Made of long needle pine and reed grass in South Carolina, circa 1880. The hooplike handle was designed so that the basket could hang from a hook in the kitchen ceiling. This style of basket weaving was brought to South Carolina from West Africa. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

As mass food delivery and marketing systems change the diets of all Americans, the feasts that bring together African Americans, particularly those with cultural roots in the South, provide continuity in African American traditional core foods. As long as festive occasions and the rituals that accompany them continue, those foods will continue as well.

## CAJUN COOKING

Cajun cooking is a regional cuisine native to South Louisiana. Traditional Cajun cooking developed in a diverse and abundant natural environment and a multiethnic though predominantly French Catholic social environment. In the narrowest sense the word "Cajun" refers to descendants of eighteenth-century Acadian settlers expelled from Canada who eventually settled in South Louisiana among a multiethnic French-speaking population, including people of French, African, Spanish, German, Native American, and other descent. Eventually the Cajuns (short for Acadians) dominated twenty-two parishes of South Louisiana, now called Acadiana. They lived in relative isolation until the twentieth century, when the outside world came to Cajuns in the form of compulsory English education, the oil industry, World War II, mass media, and an influx of outsiders bearing a standard American mass culture. Like immigrants from foreign shores, Cajuns found themselves in a new world of change. Cajun culture was a source of scorn by outsiders and an embarrassment for many insiders, and French speaking declined.

However, a revival of Cajun culture gained steam in the 1970s with the creation of French programs in the schools, a general attention to cultural expressions (music, food, and so forth), and a rise in pride in being Cajun. Part of this pride of identity is as a people who are highly sociable, who know how to enjoy life (*joie de vivre*), including the enjoyment of food, and who know how to prepare food that is exceptionally good. It is fitting that Cajun cooking has become a major cultural export and Cajun chefs have become high-profile media personalities.

### Ingredients

In the past, small farms produced pork and poultry, while beef was more common in the southwestern part of the region. People raised corn, greens, okra, peppers, mirliton (chayote), seasoning vegetables (onions, peppers, gar-

Jambalaya is the great classic of Cajun cooking. Its main ingredients are rice, sausage, and chicken. © OWEN FRANKEN/CORBIS.

lic), and more. Rice, the preferred grain, was raised in some areas and imported in others. Native Americans taught the use of filé powder, made from sassafras trees, for gumbo. Hunting, fishing and gathering in the bayous, swamps, and Gulf waters provided ingredients such as crawfish, crab, shrimp, finfish, turtle, alligator, venison, squirrel, and other game.

In the past it was necessary for Cajuns to be competent in the various environments to acquire food, and it was necessary to know how to process it for cooking. Today, most food is purchased at grocery stores, yet the traditional subsistence skills are symbolically valued and often practiced as recreation (hunting, fishing, gardening) or shown off at festivals (skinning furs, opening oysters, butchering a hog).

### Cooking Aesthetics

The aesthetics of traditional Cajun cooking demand that foods have strong, intense flavors. Strong flavoring comes from the use of seasoning vegetables (onion, bell pepper, garlic, celery) and from the careful browning of ingredients. Gumbo and other sauce-based dishes begin with a flour-based roux that is slowly browned to a dark color. Seasoning vegetables are browned. Coffee is dark-roasted. The use of cayenne and other hot peppers intensifies flavor. The proportion of hot pepper varies throughout the region and among cooks.

Cajuns say good food takes time, and many dishes require long simmering that follows slow browning. For example, gumbo, a soup, or stew that will be served over

Cooked crayfish, known locally as crawfish (or sometimes "crawdads"), are a Louisiana bayou specialty. They are traditionally served on newspaper. © NATHAN BENN/CORBIS.

rice, is simmered for hours until the ingredients soften and break down.

Major dishes reflect the practice of combining a flavorful multi-ingredient item with a bland staple, usually rice. Gumbo (of many varieties), étouffée, sauce piquant, and fricassée are served over rice. Jambalaya and rice dressing contain rice. The pattern occurs in less obvious forms, such as rice-containing boudin sausage (the "Cajun fast food"), corn bread dressing, boulettes (rice and meat or seafood balls), vegetables stuffed with seasoned meat and corn bread, and crawfish bisque, which contains cleaned crawfish heads stuffed with a dressing mixture.

### Community Food Events

Community food events include boucheries, cochon de laits, rural Mardi Gras, and festivals dedicated to certain foods. At old-fashioned boucheries families took turns butchering a hog, then cooking or distributing the perishable meat for quick use. A modern family boucherie is a party at which a hog is butchered, cleaned, and converted to various dishes, including boudin sausage, cracklings, hoghead cheese, backbone stew, chaudin (stuffed stomach), rice dressing, and cuts for the freezer. A party called a cochon de lait is a pig roast, a scaled-down version of a boucherie. Rural Mardi Gras involves gathering the ingredients for gumbo, including live chickens, by riding horses or trucks from house to house, begging for ingredients, and performing antics. Women cook the gumbo for the night's dance at a community kitchen. Throughout Acadiana festivals are dedicated to food as prepared dishes or major ingredients, such as crawfish, gumbo, sauce picquant, boudin, shrimp, rice, and so forth. Festivals usually include eating contests and food preparation demonstrations.

In both traditional and modern Cajun culture, food is a center of attention, something to brag about, something to enjoy, and something to center social events around. Both men and women cook, and men are often the star cooks at larger social events. A man's outdoor kitchen is as elaborate and well equipped as the owner can afford.

### Crawfish Boils

The quintessential Cajun food event is the backyard crawfish boil. In spring people catch or buy live crawfish and boil them outdoors with cayenne pepper and vegetables (corn on the cob, potatoes, carrots). The hot crawfish and vegetables are poured onto newspaper-covered tables. People peel the crawfish by hand to extract the tail meat and often suck the heads for additional flavored juices. Crawfish boils are extended family events but also events that outsiders to the region are likely to be invited to. At a crawfish boil food is a boundary marker that positively shows that Cajuns are competent and sociable. Outsiders often have difficulty peeling the crawfish or tolerating the hot pepper, and many are squeamish about boiling live animals or about eating what looks like an insect. The outsider (in the past often the more powerful or wealthier immigrant from the dominant American culture) is the novice, and the Cajun is the skilled one, a friendly yet superior host teaching how to peel and eat crawfish. Once a poor people's food, scorned by outsiders, the crawfish has become a symbol of Cajuns as well as a relatively high-priced ingredient sometimes used in nontraditional dishes such as crawfish Newburg or crawfish pizza.

### Cajun Cooking Gains Fame

In the 1980s trained chefs raised on Cajun cooking, such as Paul Prudhomme and Alex Patout, brought their food to the nation through restaurants, cookbooks, television, and public appearances. Cajun cooking became famous, even faddish. Cajun dishes appeared on menus far from Louisiana with varying quality. Fast food chains featured "Cajun" items. The number of food manufacturers in Louisiana multiplied, as did the number of restaurants catering to tourists. Internet sites sell Cajun ingredients and prepared dishes for overnight shipment. The non-Cajun Emeril Lagasse promotes Cajun dishes on television and in cookbooks, and tourism advertising focuses on Cajun cooking as a major reason to visit Louisiana.

## CALIFORNIA AND THE FAR WEST

California mirrors the history and culture of many states in the Far West. Like the states in the Southwest, California was first settled by the Spanish from what is now Mexico, but it received many of its subsequent settlers from the eastern United States during the Gold Rush of 1849. California's population includes descendants of Russian settlers, as do the states of Oregon and Washington. Like Idaho, Nevada, Colorado, Wyoming, and Montana, California is home to Basque families, many of them sheepherders, whose ancestors came from the Pyrenees Mountains of northeast Spain and southwest France. Chinese laborers who came to the West to build railroads settled in many small towns and founded businesses, eventually creating the great California Chinatowns of San Francisco and Los Angeles. California also encompasses many of the agricultural activities of other Western states, including citrus growing, also found in Arizona, and wine making, a prominent industry in Oregon and Washington. Fruits and vegetables that are grown in the Imperial Valley of California in winter hit their peak growing seasons somewhat later farther north in the San Joaquin and Sacramento valleys; Oregon and Washington follow even later. The American West could be said to begin where the Great Plains meet the mountains of the Continental Divide. From that point west, all streams flow in the general direction of the Pacific Ocean. From there ranges of mountains separated by broad, fertile valleys or deserts stretch across the land until, after the final range, the land, moist from winter storms and fog and rich from the great river bottoms, drops gently to the Pacific Ocean.

The great majority of the population in the West is concentrated along the Pacific Coast, yet cities like Denver, Salt Lake City, and Las Vegas grow each year, as the population of the United States moves into the Sun Belt in ever-greater numbers. The states of the West adjacent to California and the Pacific Northwest contribute greatly to the character of the Far Western states, because it is through them that many of the settlers migrated from the East on their way to the Pacific's shores. This region is also home to its first settlers, the Native American nations, whose ancestors, in prehistoric times, are thought to have crossed the land bridge from Asia into what is now Alaska. These nations and tribes have made a significant contribution not only to the development of foods in the region, but also to its artistic and spiritual elements.

It is misleading to categorize the food and culture of the Far West by state lines or even by cities or small communities. Cultures rarely start and stop at administrative

boundaries. Traditions and tastes spread with far greater subtlety as groups move from one community to another, not only taking with them food that has always been a part of their lives but also adopting foods and flavors along the way. The largest cities of the West are cosmopolitan places where many ethnic groups practice a broad variety of food traditions. Most towns and villages have food and culture practices similar to those of larger cities. In addition, many families of specific ethnic descent do not eat the foods of their own tradition every day, but enjoy exploring the foods of other cultures or foods generally considered "American." It is most often at various festival times that ethnic groups celebrate their heritage, whether it is the festivals of individual pueblos in northern New Mexico or a Greek Orthodox festival held for the entire community on a specific saint's day. The Far West can be grouped into four general areas for the purposes of discussing food and culture: The Mountains, the Great Southwest, California, and the Pacific Northwest. (The Southwest is also covered in more detail in a separate article by that title.)

## The Mountains

The states of Montana, Wyoming, Idaho, Nevada, Utah, and Colorado are punctuated by broad expanses of plains at the easternmost extent, leading to ranges of mountains separated by broad expanses of farming or ranch country. The food of the region is reflected in the activities that once took place there or in current lifestyles. After the Native Americans, the first settlers were trappers seeking furs. They were followed by settlers who came west in the mid-1800s following the Lewis and Clark Expedition (1804–1806). Mining exploration took place throughout the region in the nineteenth century. At the height of mining activity, larger mining towns possessed hotels and restaurants with menus to rival those in long-established cities, and the finest performers played in the local opera houses.

Large ranches, which raised cattle and sheep, were established in the nineteenth century followed by the smaller farms of homesteaders. Food in the ranch house or farmhouse was simple, reflecting both the Yankee origins of the settlers and the distance consumers lived from the sources of supplies. Early settlers subsisted on salt pork and beans, supplementing their diets with fresh foods if they could find them. Quick breads were made either using a kind of baking powder called *saleratus* or from a sourdough starter. When a steer or sheep was slaughtered, every part of the animal was put to good use. The huge extent of large ranches dictated the use of portable, compact camp kitchens called chuck wagons, which could be moved from one place to another to feed cowboys while they were working away from the main ranch buildings. The Dutch oven played a versatile role both in the home and in chuck wagon cooking. Over the coals of a fire it was an excellent vessel for making all kinds of stews. Buried in the coals, the Dutch oven served

literally as an oven capable of producing biscuits, cobblers, and other shortbreads.

What marks the region today are foods that can be enjoyed in the outdoors while hiking, fishing, river rafting, skiing, or camping. Freshwater fish, especially trout, and game are plentiful. While camp food tends to be the simple fare like beef stew inherited from the English, Welsh, and Yankee settlers, it is sometimes enhanced by experienced camp cooks, who produce creative dishes like lasagna made with dried *spaghetti* pasta sheets and reconstituted dried shiitake mushrooms in Dutch ovens over their campfires. Restaurants in major cities of the Mountain region offer many different kinds of cuisine to sophisticated diners.

### The Southwest

The Southwest encompasses New Mexico, Southwest Texas, Arizona, and the southern part of Colorado settled by the Spanish. The distribution of what is considered “traditional food” of the Southwest (a combination of Native American food and food adapted from Old Mexico) is not uniform, but instead is reflected in the areas that have been settled the longest. For greater detail on this area, see the separate article on the Southwest.

One aspect in the history of the Southwest that affected the growth of food culture throughout the West by introducing refinement in menu offerings and service was the Harvey House restaurant chain established along the line of the Santa Fe Railroad. Here entrepreneur Fred Harvey established restaurants that served train passengers at scheduled stops. A sophisticated menu was offered, and passengers made their choices en route. The orders were forwarded by telegraph to the restaurant so that the food was ready to be served when the train arrived. Passengers were served in the restaurant dining rooms by uniformed young women who had been recruited from respectable eastern families. This effort led to greater expectations for quality food and service throughout the West. In addition, many of the young women stayed and married business and professional men, contributing to the character of many of the cities in the area.

### California

Contemporary California is a land of dramatic contrasts, from the richly populated coastline to the sparsely settled inland deserts; from the highest point of land in the contiguous United States (Mount Whitney) to the lowest (Death Valley); from the hot dry interior to the cool, moist, and sometimes foggy seacoast. In the San Joaquin and Imperial valleys, where fields are irrigated, vast amounts of produce are grown for markets throughout the United States. Lettuces with names like red leaf, oak leaf, and curly leaf grow near other table greens with names like radicchio, treviso, and arugula, reflecting their French and Italian ancestry.

Table corn and table grapes are grown in California's Central Valley for consumption in several western states. In the microclimates near the coast, delicate produce is raised for sale at local farmers' markets. Some communities are known for specialized crops: Gilroy claims the title of Garlic Capital of the World, and Castroville, near the coast above Monterey Bay, boasts proudly of its artichokes. Ingredients indigenous to California's land and seacoasts include soft fruit, stone fruit, nuts, grain, game, cattle, poultry, fish, shellfish, and olives. Also grown are avocados, figs, pomegranates, persimmons, citrus, almonds, asparagus, strawberries, and dates.

*The settlement of California.* Spanish settlement in California began in the sixteenth century with military and missionary expeditions from what is now Mexico. Spanish missionaries often resettled Native Americans near their new missions, sometimes giving a tribe a new name to match the name of the mission. Civilians came with these expeditions and established the great land-grant ranches of early California, bringing with them food traditions of Spain, tempered by years in Mexico.

Some settlers came by sea. Russian families settled in Northern California and farther north in Oregon and Washington. Basques from the Pyrenees mountains of northwestern Spain and Southwestern France settled to grow sheep in eastern mountains of the state, bringing with them their special versions of shepherd's bread and oxtail stew. With the discovery of gold in 1849, people of all backgrounds moved west, many staying to take up some activity other than mining. Many Chinese provided labor for the construction of the railroads.

In the twentieth century, California's population grew tremendously, and cities like Los Angeles, San Francisco, and, somewhat later, San Diego expanded to accommodate larger numbers of people and their needs. Today the state is home to a considerable portion of the aeronautical industry, film and television production, some large military installations and a great diversity of technical development, especially in the field of computing. New residents came from Asia, eastern Europe and the Middle East. Chinatown in San Francisco is one of the largest in the United States, bringing with it much excellent food and sources for ingredients. Los Angeles has its own Chinese community as well as a well-established Vietnamese community. The Los Angeles suburb of Glendale is host to a large Armenian enclave with its own supermarkets and its own hospital.

*California foods.* Food availability in California makes cooking at home and dining out a pleasure. The broad, year-round availability of good fruits and vegetables, seafood, poultry, locally grown rice (including exotic types), and many other products gives cooks and chefs enormous inspiration. Fine fresh ingredients have always been appreciated in California, as is evident from California cookbooks published in the late nineteenth and

early twentieth centuries. In the last quarter of the twentieth century, a champion of these products, Alice Waters of the restaurant Chez Panisse in Berkeley, launched a renewed appreciation of locally grown ingredients acquired directly from producers, a move that ultimately inspired the growth of local green markets across the entire United States. The emphasis on freshness and proximity to the buyer is reflected in the cuisine of many of California's restaurants, now emphasizing the uncomplicated flavors of ingredients in season.

Some traditional dishes in California reveal the origins of its inhabitants. *Cioppino* (a tomato-based seafood soup) is the child of Italian immigrants who became fishermen in San Francisco and the Monterey Peninsula. Another dish, a product of nineteenth-century San Francisco in gold-rush days, is hangtown fry (a combination of fried oysters, crisp bacon, and scrambled eggs often served as a special breakfast). Mexico's influence, both old and new, can be seen in the Mexican food of Southern California, where flavors and textures of the food of the Mexican state of Baja California are reflected in such simple but excellent fare as shrimp or fish tacos wrapped in soft, warm tortillas and garnished with shredded cabbage.

Despite a frequent focus on the coastal cities of California because of their large populations, there is much to California that is neither coastal nor urban. The deserts along the borders of Arizona and Nevada are dry and desolate. Where water is available, ranches like those in the Mountain States and in the Southwest continue to flourish, raising cattle and sheep. Where Basque families have settled, they have established restaurants featuring the traditional foods of their culture. Food is served in many courses, family-style, and includes hearty stews with sweet peppers and Basque sheepherder's bread. Major inland agricultural centers are large farm-oriented operations. Others, catering to the demand for organically grown produce or specialty items, employ methods imported from Asia and other countries and do much of their work by hand.

In the northwestern part of California, where giant redwoods populate the forests, the rainfall may exceed one hundred inches a year, too wet for most farming but an exceptional climate for fresh wild mushrooms, which are gathered by experts who have their own special spots that only they know. The mushrooms are then passed on to produce brokers to sell.

**Wine.** The California wine industry produces wines to complement the breadth of California food. Although the wine industry in California burgeoned after World War II, it actually was begun in the early twentieth century, surviving the effects of Prohibition. The state's many hills and valleys are home to microclimates that give unique character to the many varieties of wine grapes grown locally. Best known of the regions are the Napa, Sonoma, and Russian River valleys of California north of San Fran-

California should be called the Salad State, for it has created a whole health cuisine based on fresh greens and vegetables. Its most famous salad is Caesar Salad, which is now found on menus throughout the United States. When properly made, Caesar Salad is prepared with great flourish by a waiter at tableside. PHOTO BY ANDRÉ BARANOWSKI.

cisco, and the Santa Ynez Valley north and east of Santa Barbara, but other vineyards abound in Monterey County and even as far south as Temecula, near San Diego. Wines made in the state have won many awards in "blind" tastings against some of the finest wines in the world.

### The Pacific Northwest: Oregon and Washington

Like California, both Oregon and Washington are dry in the eastern portion and more humid in the west and along the seacoast. And, as with California, these states are rich in fresh fruits and vegetables, excellent fish and shellfish, quality meats and poultry, and outstanding wines. Each state has its own special character, dictated by the climate and latitude.

Oregon was founded at the end of the Oregon Trail, a two-thousand-mile route from Missouri that was followed by thousands of emigrants, primarily from the 1840s to the 1860s. From the mouth of the trail poured settlers from the Midwest and the East, bringing with them architecture and foods of their previous homes. Foods learned along the way also became a part of the culinary repertoire, with desserts like cobblers, popular

because of the ease of producing them and the abundance of berries in the area. Cherries, blackberries, loganberries, raspberries, and blueberries appear as summer progresses. Occasionally, blueberries and quail are raised together, the berries providing some of the food for the quail while also enhancing the taste of the flesh of the bird as well. Oregon's eastern farms and orchards produce extraordinary pears and other cool-weather fruit.

Some prominent restaurants in Oregon have chosen to celebrate local foods and wines on their menus, featuring the excellent oysters that are harvested in the area, or farmstead cheeses and local wines.

Aquaculture plays a large role in the production of oysters, mussels, and Atlantic salmon in the Pacific Northwest. Restaurants and stands offering shellfish may have four or five varieties of oysters available for tasting.

Oregon's and Washington's wines are almost as well known to many Americans as the wines of California. Many of the smaller productions rarely leave the state or are eagerly purchased by knowledgeable wine shop proprietors and sommeliers (restaurant wine stewards). Oregon wines include exceptional ones made largely from the pinot noir grape and the cabernet sauvignon grape, both of which develop well in cooler climates.

Like Oregon, Washington's coastal area is home to growers of all kinds of crops, including a rich supply of soft fruit, that require a mild climate. The eastern part of the state is famous for its apples. Washington is also well known for its salmon production and nearly as well known for its smoked salmon as its fresh fish. The Ballard area of Seattle is home to many Scandinavians, whose emigrant parents brought with them the skills for both hot and cold smoking.

While New England Yankees, Scandinavians, and Russians were some of Oregon and Washington's first settlers, the Asian population has contributed greatly to the area in terms of food culture. One historian referred to the region as less a melting pot than a stir-fry. New residents to the region have come from Southeast Asia and also from Hong Kong during the period when it was becoming a Special Administrative Region (status conferred in 1997) of China.

Native American food traditions have considerable influence in Washington and Oregon, where salmon is split open, stretched on wood racks, and roasted before an open fire. The salmon plays a similar sacred role in the Pacific Northwest as corn does for the Native Americans of the American Southwest.

Also a part of the tradition of Native Americans in the Pacific Northwest is the "potlatch" gathering, celebrating wealth sharing, prosperity, and overabundance. The word "potlatch" comes from the Nootka-Chinook *patshal* ("gift"). The largesse demonstrated at these gatherings is a demonstration of success as well as an attempt to outdo the host of the previous potlatch feast.

While permanent and temporary markets abound in the coastal regions of Washington and Oregon, no place represents the bounty of the area quite like the Pike Place Market in Seattle. This open market is active every day, featuring the freshest of fish and shellfish, vegetables and fruits in season, and other ingredients, as well as flowers and crafts. Permanent indoor shops in the complex sell many items other than those related to food, and shops around the market have expanded into blocks to the east, but the array of ingredients for the dishes of many cultures remains a main attraction and represents a microcosm of the food culture of the region.

#### ETHNIC CUISINES

"Ethnic food" has been used colloquially for a wide variety of foodstuffs, virtually any that can be identified in the public mind with a foreign source or a American minority group. In the narrower ethnographic meaning, which will be employed here, however, it pertains only to food prepared or consumed by members of an ethnic group as a manifestation of its ethnicity. Thus it would not be an appropriate term for most foreign food eaten in a foreign land, fusion food as prepared by some innovative chef, Italian food as prepared by Greek restaurateurs, sushi prepared by a non-Japanese American housewife, or food purchased from Taco Bell or Pizza Hut, though it is sometimes extended to all these. Unfortunately, there is no clear cut universally accepted definition. In the end ethnic food is food that members of

an ethnic group consider their own and that others attribute to them.

Most social scientists agree that the ethnic group is a social category defined by any one of a variety of criteria, including country of origin, physical features such as skin color, ancestral language, religion, or some combination of these. Ultimately ethnicity is a matter of identity—recognition of the social distinction by both members of the group and outsiders. Although ethnicity has to do with social not cultural categories, members of each group inevitably participate in a subculture that is more or less different from that of those outside the group. Food and foodways (by which is meant that entire complex of ideas and behaviors associated with food) is a particularly important component of these cultural differences.

### Cultural Adaptations

Ethnic foodways, like other American foodways, are in constant flux. Changes in immigrant foodways are part of a larger process of social and cultural change.

The process by which immigrants become ethnic Americans is long, gradual, and complex. One can think of this as ethnogenesis or the creation of a new social group. Along with the development of a new ethnic group is a parallel development of a new subculture, including new foodways, that both symbolizes the group's uniqueness to its members and marks off its social boundaries. The new subculture is created in the American context, altered to a greater or lesser degree from what was known in the homeland. Polish Americans (and any other ethnic group can be substituted here) are not the same as Polish in Poland, and Polish American culture is different from the culture(s) found in Poland. Neither do Polish Americans belong to some culture somewhere between American and Polish, as might be surmised from the overly simplistic models of acculturation that have so often dominated thinking on the subject. Ethnicity exists only in specific contexts where one sort of people (Us) is brought into regular and intimate contact with people of other sorts (Them).

It is impossible to re-create exactly in America the foods of one's homeland, no matter where that might have been. Ingredients as basic as flour are different in the United States, yielding different results. Many ingredients are unobtainable here. The white cheese (*beli sir*) of Bosnia that Bosnian refugees require for one of their most common dishes, *sirnjaca* (a sort of cheese pie), is not available in the United States. Many Bosnians say *sirnjaca* is the food they miss most. They cannot even make cheese or the many other milk products that were an important part of their diet in Bosnia, because unpasteurized milk is unobtainable in the United States.

The same is true of the equipment and implements of cooking. The national dish of Bosnia, *Bosanski lonac*, is a stew of combined meats and vegetables slow cooked in

Foreign cuisines are often altered once they are transplanted to the United States. This Chinese-American cookbook by M. Sing Au published in 1936 features many dishes unknown in China, such as Lantern Party Salad and Chop Suey Soup. ROUGHWOOD COLLECTION.

a special earthenware pot. The special pot is so much a part of the dish that it is named after it; *lonac* means pot in Serbo-Croatian. These are used for no other purpose and are often treasured heirlooms. One Bosnian American housewife related that hers was a gift from her father, who had given each of his daughters one he had brought back from a distant market where they were sold. She had been forced to abandon hers when she fled Bosnia. One might cook a similar combination of meats and vegetables in an aluminum stew pot, but it is not the same.

But these sorts of problems get worked out, just as they do for other aspects of life. Adjustments are made. Substitutions are found. One accepts that some favorite foods of one's homeland can now exist only as fond memories. It is this process of adjustment, the culinary dimension of an immigrant becoming an ethnic American, that is of significance here.

The process by which immigrants become ethnic begins as soon as they board the boats and planes that carry them to the New World. The incentives are somewhat different for refugees than for willing immigrants, but the process remains pretty much the same. No group of emigrants from any country represents a cross section of that country's population. They are always drawn from some regions more than others, some social strata more than others, and some communities more than others. Since each of these groups possesses a recognizable subculture (including distinctive foods and foodways), it is logical that immigrant communities cannot replicate exactly their old national culture in the New World. If most of the Italians who settle in a particular community are from Calabria, then Italian cooking in that community will surely reflect the regional cuisine of Calabria, at least in the earlier phases.

Out of immigrant culture develops an ethnic culture that differs from it in significant ways. There are several primary sources on which this developing subculture draws. The first is the culture of the homeland. One aspect of the process is an amalgamation of the local, regional, and class-related subcultures that are represented in the new community. These processes have both a public and a private face, and it may well be that they work faster in the public. In the Detroit area, Lebanese, Yemeni, and Chaldean restaurants are rapidly developing a common Arab-American menu at the same time that housewives of these same groups continue to cook distinctive national cuisines. Even though the proprietors and cooks of many Mexican restaurants have come directly from Mexico, their menus feature the same standardized combination plates of the stereotypic "Mexican" restaurant derived primarily from Texas-Mexican cuisine. This is so even when a significant proportion of their customers are also recent arrivals from Mexico. Some regional recipes or cooking techniques may be preserved as family traditions, but in general the community will reach some consensus.

A second source in the creation of an ethnic culture is the culture of mainstream America, such as it is experienced by immigrants and ethnics. An important part of the accommodation process is finding ingredients in the United States to substitute for those from the homeland that are no longer available. Hmong find aluminum foil an acceptable substitute for banana leaf when wrapping food. Serbian American cooks, like other Balkan immigrants, attempt to replicate the white cheese so important in their cuisine with some combination of cottage cheese, feta, sour cream, or cream cheese. Different combinations may be used for different purposes, but nothing tastes quite right. Other substitutions are for the sake of convenience. Norwegian Americans making *lefse* may replace freshly peeled potatoes with dried potato flakes, especially when cooking in quantity. Many Asian Indians quickly replace labor-intensive flatbreads with store-bought white bread. Still other changes have to do with

higher standards of living. Dark flour may be replaced by white flour, considered desirable but less affordable in the Old Country. Meat becomes much more prevalent in the diet of most immigrant groups.

### Creolization

The third source—too often overlooked—is the cultures of other immigrant and ethnic groups encountered in the United States. Most often immigrants settling in multi-ethnic environments will move into neighborhoods and will work in occupations associated with earlier immigrant groups. Finns, Croatians, and Italians who went to northern Michigan to work in the iron and copper mines replaced Cornishmen, some of whom became their foremen and bosses. These earlier immigrants from Cornwall became their model for American culture, and the Cornish national dish, pasty, was soon adopted by all. New Yemeni immigrants in Detroit, Michigan, moved into houses vacated by Poles, Romanians, and Lebanese who were ready to move uptown or to the suburbs. Their foreman at the auto plant is likely to have been hired from one of these previous waves of immigrants. These people of different ethnic cultures establish models of American life for the new immigrant. The Mexican immigrant who is hired to work in the kitchen of an Italian restaurant is surely affected by that experience. And when he or she takes home extra food to share with members of his or her family, they too will be affected.

The creation of ethnic culture from these various sources takes place within the particular constraints of minority life: the homesickness, the prejudice, the sense of being different, the urge to assimilate or to resist assimilation, the need to recreate the Old World in the New or to reject all possible reminders of the life that was. All these factors shape the specific form taken by the new culture. Many have come to call this process "creolization" after the term for a similar linguistic process, both of which refer to the creation of a new cultural configuration out of parts of several other preexisting cultures. Creolization may be regarded as the defining characteristic of ethnic food.

One can observe creolization in any aspect of ethnic culture, but it is particularly significant in food and foodways. There are a number of reasons for this. First, cooking and eating are expressive behaviors relatively easy to observe and, most important, heavily laden with symbolic meaning. A particular dish can evoke memories of home, family, better times, one's own place in the world. Familiar food is very much the natural way of things. In a sense, for an immigrant all the food of one's homeland is "comfort food." African Americans outside the South may pointedly eat soul food as an expression of who they are. A single dish may become the most important expression of ethnic identity, symbolizing the group and signaling to other members this common bond and by extension others, thereby reinforcing an individual's own sense of belonging. Crawfish among Cajuns and kielbasa

among Polish Americans of pre–World War II immigration serve as examples. Because cuisine is especially responsive to new environments, where some ingredients are unavailable, and because new social settings bring new ways of eating and cooking, foodways are especially quick to adapt and change. At the same time, however, perhaps no aspect of culture is so resistant to change, so tenaciously held. After all, eating is a daily reaffirmation of who you are. Generations after the loss of their mother tongues, ethnic Americans are still likely to be cooking and eating some version of the family’s “mother cuisine,” even though it may be significantly changed from food in their homelands.

The social structure of an American ethnic group is often reflected in its foodways. Some groups were ethnic minorities in the nations from which they came to the United States. Examples include Jews and Roma from eastern Europe, Hmong from Vietnam, Germans from Russia. Such groups usually develop distinct communities in the United States with foodways that are distinctive, albeit usually closely related to those of others who came from the same country. Ethnic groups are often nested, one identity subsumed within another. A person might be Sephardi in the company of Ashkenazim and Jewish when with a group of Gentiles. A Hmong might be so categorized when with other Vietnamese and Vietnamese when with other Americans. All such social differences are replicated by differences in cuisine, and these take on great symbolic importance.

Foodways serve to demonstrate ethnic community in more instrumental ways as well. Eating together at an ethnic picnic or banquet is a manifestation of group solidarity. Borrowing a start of yogurt in the Armenian-American community or for *viili* (another soured milk product) among Finnish Americans is an expression of the network of relationships that constitutes community. Receiving needed ingredients from relatives or friends still living in one’s homeland demonstrates the link to homeland that is another aspect of the ethnic community. These might be foodstuffs unavailable here, at least in the locale where the recipient resides. Similar social relationships may be enacted when foodstuffs are sent between different American communities, as when Arab Americans in Detroit’s large community send basic ingredients to relatives living in northern Michigan, where the Arab-American community is small and even the basics are unavailable.

Often foodstuffs are sent from abroad, not because the item is unavailable in the United States but because the item from one’s homeland is thought to be superior in quality. Most Lebanese Americans, for example, prefer spices and *kishik* (dried yogurt) from Lebanon. In some cases the item sent from abroad is not even considered superior but is laden with symbolic meaning. An Austrian American who receives annually a box of walnuts from home knows that they do not taste better than American walnuts and that sending them costs more than

buying them in the United States. But they come from the tree in the family homestead where he or she grew up, and no American walnut really suffices.

### Diffusion

Diffusion is rarely a one-way street. Just as members of an ethnic group are influenced in their foodways by those they live among, members of the majority population (including members of other ethnic groups) adopt ethnic foods, usually changing them in the process. Most often this involves commercialization, often initiated by ethnic entrepreneurs from within the community itself. As the process proceeds, changes in the foodstuff often transform it into something far different from the original; pizza, yogurt, and bagels come to mind.

Ethnic food has existed in America since colonists first encountered the exotic foods of local Native Americans and vice versa. But as a field of study, ethnic food attracted little interest until just prior to World War II. Most earlier commentary on ethnic food had to do with hastening its demise in the interest of assimilation. Some of the earliest work on the subject was done by Margaret Mead and her colleagues at the National Research Council’s Committee on Food Habits during the early 1940s. Their goal was to develop profiles of cultural food preferences in the United States in an attempt to better shape national policy to fit particular local situations. At first they planned to exclude ethnic food from their studies, but soon, most likely under impetus of the new world war, they began to include study of what was then called “the food habits” of “foreign background groups in the U.S.” By the time the committee was disbanded in 1942, it had produced a series of mimeographed memoranda on ethnic food.

The Federal Writers Project (1935–1943) generated further study of ethnic foodways as one part of its studies of regional cultures. *America Eats*, more specifically devoted to foodways, was a spinoff. The goal was to publish a book by that title comprising a comprehensive account of the history and ethnography of culinary traditions in the United States. Although it was to be regionally organized, research inevitably included ethnic foodways. A tentative table of contents included such items as Minnesota’s lutefisk dinners, Mexican backyard barbecues, and North Dakota’s Scandinavian picnics. Due to increasing concern with the war effort, the project was abandoned in 1942, and little of the research was ever published.

Nearly all of the work on ethnic cuisines up to this period was descriptive in nature and applied in purpose. One of the first analytic papers on the intersection of food and ethnicity was by John Bennett, Harvey Smith, and Herbert Passin in 1942, “Food and Culture in Southern Illinois,” in which they demonstrate how diet is shaped by culture in a region shared by Germans, African Americans, and old-stock Americans.

The revitalization of ethnicity in the United States initiated by the African-American civil rights movement and further stimulated by activities surrounding the bicentennial brought ethnicity to the fore of American consciousness, both within and outside ethnic communities. As a multicultural model of America developed and ethnic pride was manifested, retention of traditional foodways came to be regarded as a positive rather than a negative attribute. Ethnic food was further popularized during the explosion of interest in food during the 1960s, 1970s, and 1980s and the general search for new and exotic foods. This surge of interest was felt at both the popular and scholarly levels. Ethnic food continues to be a frequent and important research topic for folklorists, cultural anthropologists, and culinary historians.

#### HAWAII

Located almost dead center in the North Pacific Ocean—2,500 miles west of California—Hawaii consists of a string of 132 coral and volcanic islands extending some one thousand miles from the Big Island to Wake Island. Centuries of volcanic activity have deposited layers of ash that have enriched the soil. Strong sun combined with moderate temperatures and plenty of rain have produced a long growing season in the midst of a tropical paradise—a paradise that lured nineteenth-century European and American merchants and adventurers interested in exploiting Hawaii's natural resources. One result was an economy dominated by King Sugar, which employed waves of immigrants to do the backbreaking work refused by native Hawaiians.

This successive importation of workers left Hawaii with a thriving *mélange* of cultures, each of which made its own contribution to the twentieth-century phenomenon known as Local Food. A Creole mixture of different cuisines (including Polynesian, Japanese, Chinese, Portuguese, Korean, and American), Local Food is centered on carbohydrates—an ancient Hawaiian quest.

#### The First Polynesian Immigration

When human beings originally landed on Hawaiian shores between 300 and 500 C.E., having probably sailed roughly two thousand miles from Samoa, they encountered over a hundred species of birds, including large fowl, abundant fish and shellfish in shoreline reefs and lagoons, a few fruit trees at high altitude, ferns, several kinds of *limu* (seaweed), and nearly a thousand flowering plants. These species had arrived gradually on trade winds or sea currents and had evolved in isolation over hundreds of thousands of years.

But the same geologic conditions—deep canyons, high cliffs, forests, bogs, and a wide variation in barometric pressure, rainfall, temperature, and wind—that produced Hawaii's unique flora and fauna had also lim-

Taro is one of the most important food plants in traditional Hawaiian cookery. The root is used in making *poi*, while the stems (shown here) can be cooked as a green vegetable. © DOUGLAS PEEBLES/CORBIS.

ited its native foods. Hawaii's astonishing diversity included almost no edible vegetation and no source of edible carbohydrates. Luckily, the early Hawaiians brought at least twenty-seven kinds of foodstuffs, including the coconut, breadfruit, sweet potato, banana, sugarcane, arrowroot, wild ginger, mountain apple, and taro—much revered by the ancient Hawaiians, who pounded the roots into a paste, *poi*, that remains a starchy staple today. In addition, they imported pigs, chickens, and dogs. By mistake, they brought along rats.

They lived well on their isolated islands. They ate many foods raw, including some fish. Other food was cooked in *imus*, earthen pits lined with *kiaʻwe* wood and lava rock. They prepared for bad weather by drying and salting fish. While they had no distilled liquors, they used the roots of *awa* (kava) and *ti* (a lily relative) to brew narcotic drinks.

### The Second Polynesian Immigration

The early Hawaiians were legendary seafarers who had sailed thousands of miles using the stars, sun, winds and currents, shifting cloud masses, and bird flights. There is some evidence that they continued to sail their hundred-foot-long outrigger canoes to distant islands in the Pacific, bringing back food, plants, and spouses.

Between the eleventh and thirteenth centuries, aggressive, roaming Polynesians from Samoa and Tahiti settled in Hawaii and established a feudal regime overseen by their nobles and priests. The new feudal lords

protected the ancient stonewalled fishponds, which yielded five thousand pounds of fish daily, and they enhanced traditional irrigation systems by building elaborate rock terraces.

They allocated property rights fairly widely, enabling most Hawaiians to eat well. The new rulers also enforced many complex *kapus*, or taboos, some of which helped manage scarce resources. Their system of land division is cited by biologists for its habitat protection. The huge freshwater and seawater fishponds were integrated with agriculture, and river valleys were managed as unified systems. The upland forest, left uncut by taboo, helped supply rivers with nutrients for downstream fields and fishponds. Seasons for gathering or catching scarce food or game were strictly enforced. Some taboos were exclusionary, particularly toward women, who were barred from preparing food for or eating with men. They were not allowed to eat the best foods, such as coconuts, shark meat, and pork. Breaking the taboos was punishable by death.

### The Arrival of Westerners

By the time Captain James Cook landed on Kauai in 1778, Hawaiians had developed a comfortable economic system overseen by a feudal government. The Westerners would soon change all that.

Cook was the first of many seamen to use Hawaii as a way station to refuel and resupply ships in the middle of the ocean. He was renowned for having solved the

The warm waters off the Hawaiian islands offer a large variety of colorful tropical fish that are prized in local cookery.

© DOUGLAS PEEBLES/CORBIS.

immense problem of scurvy among sailors, which he concluded was due to a lack of fresh fruits and vegetables. At every port he sought out fruit (particularly citrus), vegetables (including onions and new potatoes), fish, and meat.

The lush islands had much to offer Cook, who ruthlessly took immense amounts of food on his first trip, exploiting Hawaiian generosity. While Hawaiians had welcomed him with a lavish feast on his first visit, they knifed him to death when he returned in 1779.

Cook gave Hawaiians the first specimens of Western flora and fauna—goats, English pigs, and melon, pumpkin, and onion seeds. Close behind him came whalers and traders at the end of the eighteenth century, then the American missionaries, mainly Congregationalists, in 1820.

The missionaries introduced the church, school, printed word, woolen clothes, wood houses, and many foods. They sought to clean, clothe, and feed Hawaiians according to Christian standards to make them more responsive to the gospel. Beef was already available because cattle had been imported in 1793 by Captain George Vancouver, who had convinced King Kamehameha to permit women as well as men to eat it, as long as they ate from different cows.

The Congregationalists brought their prized New England foods—potatoes, apples, salted cod, corned beef, butter, and cheese. Food became a vital tool in Christianizing Hawaiians and turning them away from their traditional practices. When Queen Regent Kaahumanu converted to Christianity in 1824, she held a service at the edge of the Halemaumau fire pit sacred to the goddess Pele. Declaring her allegiance to Jehovah, she ate ohelo berries, which were both sacred to Pele and taboo to women. Not a murmur was heard from the volcano goddess.

### Dominance by Plantations

Meanwhile, Westerners had also introduced their diseases, which reduced the native Hawaiian population from an estimated 300,000 at Cook's arrival to 60,000 by the mid-1800s and 40,000 by the end of the century. The rapidly expanding sugar industry—many plantations were owned by missionaries and their descendants—imported thousands of Chinese and then Japanese laborers to replace the Hawaiians. Just as the arrival of Westerners nearly wiped out native Hawaiians, the domination of agriculture first by sugar and later by pineapples wiped out the Hawaiian system of small farming overseen by religious laws, which regulated both hunting and farming.

Although wealthy whites received important administrative posts in the Hawaiian government, thereby governing indirectly, they became increasingly unhappy with the monarchy, which they deemed corrupt and inefficient. They wanted secure property rights to build their plantations and they wanted no restrictions on their importation of labor. They overthrew the monarchy in 1893. (Hawaii became a U.S. territory in 1900 and the fiftieth state in 1959.)

Between 1852 and 1930, Chinese, then Japanese, Okinawans, Norwegians, Germans, Koreans, Puerto Ricans, Portuguese, and Filipinos were imported by the immensely powerful factors that supplied plantations with all their needs, including workers. The workers wanted their own food, and the plantation stores procured it from abroad if it could not be grown locally. What could be grown was. Thus rice became Hawaii's third most important crop, after sugar and pineapples. Most immigrants brought seeds with them, though they could not always get them to grow. Manufacturers sprang up to produce tofu, noodles, kimchi, and sake.

Into this diversity came yet another set of missionaries—home economists, most trained by Columbia University's Teachers College. Convinced of the legitimacy of their field, the home economists taught at the newly established University of Hawaii, a land-grant university. Working with the electric and gas companies in the 1920s, they developed recipes that required the new appliances—stoves, ovens, and refrigerators. They promulgated the nutritional messages and agricultural advice of the Extension Services. They catalogued locally grown tropical foodstuffs and analyzed the nutritive values of the Hawaiian diet. They encouraged the consumption of American food, including milk, which many adult Hawaiians were unable to digest properly. They trained school cafeteria managers to produce Salisbury steak, mashed potatoes, and creamed corn. And they wrote the first cookbooks on Local Food.

### The Development of Local Food

Hawaii's sad story of colonial exploitation is tempered by its exuberant ethnic diversity, nowhere to be found more clearly than in food. Calling themselves "locals," Hawaiians call the food they eat "Local Food," a term that most

food writers now capitalize. Identified in the 1920s as a distinct phenomenon, Local Food mixes dishes from each of Hawaii's ethnic groups into unique forms, most famously the plate lunch served at diners and lunch wagons. This includes two scoops of sticky rice, meat cooked Asian style, and macaroni or potato salad—all eaten with chopsticks. Local Food includes shaved ice, SPAM wonton, *malasadas* (Portuguese donuts), saimin (noodle soup), crack seed (Chinese preserved plum), and butter *mochi* (a rice confection).

Except for indigenous coconut and banana trees, most foods associated with Hawaii are imported. The first immigrants, the Canoe People, brought with them twenty-four different plants. Since about 1800, a large number of additional plants, including pineapples, papaya, avocado, guava, sugar cane, coffee, and macadamia nuts, were introduced. Even the Kiawe tree—a variety of the family that includes mesquite, and is now rampant throughout the islands—was introduced.

Hawaii's premier agricultural product in modern times, the pineapple, is a native of Paraguay. Although introduced in the early 1800s, it was not commercially successful until the early twentieth century, when it was canned and sold to U.S. markets. By the early 1950s, almost 75 percent of pineapple on the world market was Hawaiian, thanks to inspired advertising. Hawaii has no canneries left today. Its entire crop is distributed fresh, accounting for about one million tons of fruit, or one-third of the world's consumption.

The highly prized Kona coffee, imported by Don Francisco de Paulay Marin in 1828, thrived in Hawaii's volcanic soil, enhanced by local altitude and climate. Simultaneously mellow and robust, Kona beans became renowned worldwide after the market crash of 1899, when the large plantations began leasing their lands to families of workers, who greatly improved the methods and quality of production. Many of those families are now in their fifth generation, producing some two million pounds a year. In the 1990s, coffee began to supplant the sugar cane plantings on several other islands, including Kaua'i, Maui, Moloka'i, and O'ahu—which now surpass Kona in total production. Most Hawaiian beans are sold for blends. Coffee marketed as a Kona blend must be at least 10 percent Kona.

*Theobroma cacao*, a variety of criollo, was able to take advantage of the same volcanic soil and climate and thrive. Though originally equatorial, Hawaiian cross-breed cacao, which has a nutty flavor and low acidity, grows quickly in open sun. (Its equatorial competitors need shade.) Its pods are harvested early—in two years rather than five—and its trees are more productive than elsewhere, averaging a hundred pods each, or five times the world's average. The chocolate is premium grade.

While macadamia nuts were brought to Hawaii as ornamentals in the nineteenth century, they did not become a commercial crop until the 1920s. Because the nut

is very hard to crack, it is normally sold shelled. And because its production is labor intensive—one hundred pounds of harvested nuts yield only ten to fifteen lbs of edible meats—macadamias garner a premium price. Hawaii has some twenty thousand acres planted with macadamia trees today. The trees have a fifty-year lifespan.

Sugar cane, now displaced as a commercial crop, was introduced by the Polynesians. In the nineteenth century it became the islands' most significant commercial crop; it was for sugar cane that the Western economic interests eventually overthrew the monarchy.

Bananas were both indigenous and imported. With seventy varieties now grown on the island—and prestige accorded to some—Jean-Marie Josselin likens the Hawaiians' distinctions among bananas to the Eskimos' distinctions of the varieties of snow.

### Making Sense of Tourism

Since Hawaii's resident population of 1 million serves some 6 million tourists annually, the influence of outsiders on Hawaiian food can hardly be overstated. Until the late twentieth century that influence was baleful, with Honolulu having perhaps the worst restaurants of any major Western city. Even once elegant hotels like the Royal Hawaiian serve wretchedly bad meals in the name of traditional luaus—originally religious feasts of genuine importance degraded to farce by commercial exploitation.

But it is also true that many foods thought to be Hawaiian are not. Much of the so-called Hawaiian food served at Polynesian restaurants on the American mainland was invented in California and promulgated by Trader Vic's and other restaurateurs. Fried rice, satays, curries with coconut milk, rum-based drinks garnished with flowers and paper parasols, and dishes named after the goddess Pele or King Kamehameha have no real connection with Hawaii.

Since the early 1990s, however, a genuine Pacific Rim cuisine emphasizing cross-cultural influences but using local ingredients has developed. This has benefited small farmers, giving them outlets for superb fruits and vegetables—Maui onions (comparable to Vidalias), Manoa lettuce, Kahuku watermelon, Waimanalo corn, Kona oranges (a Valencia competitor) and avocados, Puna papayas, and an amazing range of seaweeds and ferns.

Meanwhile, native Hawaiians have reversed their population decline—about one-fourth of Hawaii's resident population of one million at the start of the twenty-first century claims some Hawaiian ancestry. Who is a native? One definition is that a native Hawaiian is someone who eats *palu*, a condiment made of chopped bits of fish head and stomach mixed with tiny amounts of *kukui* (candlenut) relish, chili peppers, and garlic. Not many fraudulent Hawaiians are likely to come forward to win this credential.

### THE MIDDLE ATLANTIC STATES

The waves of European ethnic settlement in the mid-Atlantic colonies in the United States prior to the Revolution produced regional culinary patterns that have influenced American cookery down to the present day. These areas of settlement have been described as "culture hearths" by folklore scholar Henry Glassie because they created a continuous emanation of influences. The cumulative effect of these culture hearths has been twofold: an evolution of distinctive mid-Atlantic foods and foodways, and a spread of this coastal culinary identity into the interior of the country, especially into the Midwest.

The succession of settlement begins with the Holland Dutch, who in 1624 carved New Netherlands out of the Hudson Valley of New York and adjoining parts of New Jersey, with significant settlements in Delaware (direct from Holland), and in Pennsylvania in the form of migrations from New York and New Jersey. The Swedes and Finns settled among the Dutch in the Delaware Valley beginning in 1638 with the foundation of New Sweden (over Dutch legal objections). All of this initial settlement, which was represented by relatively small numbers of people, was later numerically overwhelmed by large immigrations from the British Isles, headed principally by the English Quakers who founded New Jersey, Pennsylvania, and Delaware.

The Quakers themselves represented a mixture of English, Welsh, Scots, Irish, and Ulster Scotch-Irish elements, and each of these groups brought Old World foods and foodways to the region. The Quaker policy of extending settlement opportunities to continental Europeans suffering from religious persecution virtually threw the entire region open to a vast mélange of new settlers from Germany, Switzerland, Alsace, Austria, and

France. These non-English-speaking settlers created in the Middle Colonies a cultural diversity that has come to represent American food culture as a whole. Yet each group has left its legacy, the most important perhaps being the German-speaking element, which gave rise to the present-day Pennsylvania Dutch. In terms of area, the so-called Pennsylvania Dutch settlement region was about the same size as modern Switzerland and just about as varied. Close behind the Pennsylvania Dutch were the Scotch-Irish who settled the hill country of Appalachia and who created a regional culinary culture known as Cohee.

From a historical standpoint, the most recent treatment of the foods and foodways of the New Netherlands Dutch is Peter G. Rose's translation of *The Sensible Cook* (1989), which explores Hudson Valley Dutch foodways via an old Holland Dutch cookbook. The original *Sensible Cook* (*De Verstandige Koek*) appeared in 1667, at a time when Dutch gardening was undergoing a horticultural revolution. The Dutch infatuation with exotic plants and kitchen gardening was transplanted to the New World, especially through the medium of Dutch Mennonite seed and plant merchants, who controlled much of the trade with New Netherlands and the Quaker colonies to the South.

#### The Dutch Cuisine

In spite of persistent Old World contacts, New Netherlands Dutch evolved into a dialect of its own with a large

array of food concepts fully unknown to the Old World Dutch. These dishes would include *suppawn* (a type of cornmeal mush) and pumpkin pancakes, but intermingled with such Old World dishes as *olie-koecken* (a type of fat cake), soft or yeast-raised waffles, and *kool sla* (cabbage salad), served hot or at room temperature. Modern American coleslaw is probably the best known legacy of this old Dutch cooking tradition. However, the small Dutch New Year's cake called a *kookjie* has also entered standard American English under the more generic form of cookie (small cake). The true New Netherlands *kookjie* was in fact the so-called New Year's Cake, which evolved into a high art form in New York and Philadelphia. Many elaborately carved molds survive as a silent testimony to this lost art of ornamental pastry. The New York atelier of baker and mold maker John Conger produced some of the most elaborately carved molds to survive from the 1830s and 1840s.

### The English Cuisine

By contrast, the English cuisine in the Middle States, as illustrated by the Quakers of Philadelphia and Baltimore, was basically a British Isles cookery adjusted to New World ingredients and climate. Nineteenth-century Quaker cookbook authors such as Elizabeth Ellicott Lea (Sandy Spring, Maryland), Elizabeth Nicholson (Philadelphia), and Hannah Widdifield (Philadelphia) mention a number of dishes associated not only with their religious group, but with the general population at large: white sweet potato pie (Quarterly Meeting Pie to Quakers), lemon butter and rusks, and the ubiquitous dried beef gravy. This last dish, which was served over toast, was often known as "Quaker gravy" throughout the region. Its chopped beef and onion version has survived to this day under the rubric of the Philadelphia cheese-steak sandwich.

The Quaker element was especially well known for its dairy culture in the form of substantial spring houses for the production of high quality butter and cheese. Philadelphia cream cheese (a soft cheese resembling French brie) was famous in the nineteenth century, although today it lives on in name only in the form of a processed cheese spread. The rich milk and cream that produced the popular cheeses and butters of the region also served as a major ingredient in Philadelphia ice cream, at one time a highly sought-after food on the American luxury market.

Quaker farmers were also skilled gardeners and orchardists, and some, like the Bartrams of Philadelphia, Humphrey Marshall, and William Darlington, studied native plants and trees and exchanged seeds with their European contacts. The Quakers also kept up an English preference for tea-drinking over coffee. Among the urban Friends of the nineteenth century, Quaker Tea Parties were synonymous with catered balls, a menu heavy with rich cakes and fancy side dishes, and a beverage selection awash with the best wines and champagne.

A New Year's cake made from the Thomas Y. Watkins print (facing page). The cake would have been further ornamented with colored icings and gilding. PHOTO WILLIAM WOYS WEAVER.

In total opposition to this show of opulence, were Friends who promoted vegetarianism and abstinence from alcohol long before these themes became commonplace in American culture. In fact, the first health food stores were opened in Philadelphia by the Quaker Martindale family during the 1860s.

The Pennsylvania Dutch element introduced food concepts found in the traditional peasant cookeries of southwest Germany, Switzerland, and Alsace-Lorraine. The pioneer generation ate simple, one-pot meals like sauerkraut and pork or *Schnitz-un-Gnepp* (dried apples and dumplings with ham and ham stock) reproduced from the homeland. They consumed more soups than their English-speaking neighbors, as well as numerous flour-based preparations like noodles and filled dumplings. Since the Pennsylvania Dutch farmers settled in what soon became the colonial wheat belt, a vast array of pies, cakes, breads, and festive cookies were added to the immigrant menu. Outdoor bake ovens were once a common feature on nearly every farmstead in the region, and travelers through the area never fail to mention the popularity of *Lotwarrick* (apple butter), salads with hot dressings, and *Schmierkees* (cottage cheese), especially *Schmierkees* flavored with chives.

In spite of the culinary quiltwork that once represented the region, most ethnic groups did not initially like or adopt the cuisines of their neighbors, except out of necessity. Thomas Hill, a New Jersey Quaker passing through eastern Pennsylvania on his way to settle along

Watercolor of the interior of La Panetière, a 1980s Philadelphia restaurant that employed the setting of an elegant turn-of-the-century townhouse to create an intimate atmosphere. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

the west branch of the Susquehanna River, remarked in reference to the Germans: "My breakfast this morning, two cups of coffee without sugar, and three eggs; bread baked hard, and crust wet." For another meal: "Salad with milk, oil, vinegar, bonny clabber and bread; good God! How can they work so hard on such food!" A melting-pot effect did eventually overtake such aversions, especially in urban areas and in families in which intermarriage between ethnic groups occurred. This kind of hybrid mixing resulted in such regional specialties as pop-robin pudding (grated dough baked with cinnamon and butter), mush muffins (cornmeal Welsh muffins), and chicken salad served with fried oysters—to name a few.

Due to religious tolerance, this part of the United States was the first to witness many charitable food-related events, such as the church supper, fund-raising cookbooks, camp meeting dinners, and Sunday school picnics. The spread of these blue-collar social institutions was due in part to the publishing industry that once characterized Philadelphia's literary scene. Writers like Eliza Leslie and Sarah Josepha Hale gained national prominence through *Godey's Lady's Book*, a prominence the city maintained into the early 1900s with *The Confectioners' Journal*, Wilmer Atkinson's *Farm Journal*, Sarah Tyson Rorer's *Table Talk*, as well as Curtis Publishing's *Ladies' Home Journal* and *Country Gentleman*. Every one of these publications is chock-full of recipes reflecting trends in

American cookery during this period. Sarah Tyson Rorer in particular managed to take her culinary agendas well beyond the walls of her once-famous Philadelphia Cooking School. Her crossover into product promotional literature and specialized recipe books for everything from ice cream to vegetables made her a household name by 1900.

From a historical standpoint, colonial New York and southeastern Pennsylvania have left a lasting impression on American cookery via such foods as coleslaw, crullers, shoofly pie, soft pretzels, and rye whisky, not to omit New Jersey's once famous apple brandy known affectionately as "Jersey Lightning." Much of this emphasis on regionalisms has been revitalized through the efforts of the Kutztown Folk Festival, founded in the early 1950s and considered the first of its kind in the country. While the festival may attract New Yorkers in search of rural roots, the movie *The Age of Innocence* has recaptured the sumptuousness of the culinary scene during New York's Gilded Age. This was an era when American food as social display by the robber barons reached its ultimate apotheosis, since the grand dinners were also social events staged as much for the participants as for a spectacle-hungry public. In this exchange the seeds of many mythologies were sown.

### The Origin of Current Trends

It is often forgotten today that the cowboy in American mythology and the "chow" cookery now associated with cowboy fare were not created from scratch on the Great Plains, but in the townhouse study of blue-blood Philadelphia author Owen Wister. His romantic novel *The Virginian* (1902) was a launching point for this very pervasive image in American culture. Immigration has also contributed to an ongoing evolution of more recent icon foods, such as New York's bagels and Reuben sandwich and Philadelphia's hoagies (known elsewhere as grinders or submarines).

New York has evolved into a truly international metropolis with a fascinating food story that would consume all the pages of this encyclopedia. Its position on the international scene was firmly fixed after World War II with the establishment of the United Nations headquarters in Manhattan. But it was New York's role in the American culinary revolution that has had its most lasting effect on our food. The transformation of the classic French cookery of such restaurants as Le Pavillon (which opened in 1941) into the likes of The Four Seasons and the celebrated Windows on the World in the World Trade Center is the story of an Americanization process in *haute cuisine* that emanated primarily from New York City. Added to this were the TV personalities of James Beard and Julia Child, whose impact on American cookery has been fundamental. The James Beard Foundation, with its annual awards for chefs and food writers, has continued to focus on New York's leadership in many branches of American food and culture.

As a counterpoint to this, Philadelphia and Baltimore have managed to retain a regional American character, especially in terms of culinary identity. Philadelphia established itself as the American culinary capital in the early nineteenth century, with roughly one-fourth of its immigrant population either European or Caribbean French. This contributed to a Caribbean accent in its urban cookery, hence the turtle soup and peppercorn vendors. It was also the cultural mecca where the Old South wintered. Pre-Civil War Philadelphia was indeed a city whose lifeblood was derived from Southern money and shipping, which brought to its larders vast quantities of foodstuffs from Asia, the Caribbean, and South America. Its economic rival was sister-city Baltimore, which today has preserved much of its Federalist Era culinary culture as defined by the Chesapeake Bay.

Both Philadelphia and Baltimore became centers of manufacturing after the Civil War, which changed elegant streets of stately row houses into smoke-congested corridors of noise, shuffling foreign labor, and crime. The rich left for the suburbs; thus, in both cities, dining culture retreated to country houses or into the hands of dining club managers and African-American caterers. In Philadelphia, the Augustin family (originally from Haiti) became the most important catering family on the East Coast and prided itself on such specialties as oyster fritters, creamed terrapin, and rasped rolls. At one time the Augustins owned railroad cars with kitchens so that elegant meals could be served as far away as Boston, Chicago, and Washington.

It was the Chesapeake Bay that eventually saved Baltimore, because the city has revived its culinary identity within the last thirty years on such local Bay specialties as soft-shell crab, beaten biscuits, stuffed ham, sweet potato pie, and Lady Baltimore Cake (another Owen Wister invention). With the restoration of historic Society Hill, Philadelphia culinary culture was revived in the 1970s by La Panetière, the haute-cuisine launchpad for what has become a culinary renaissance in that city. Philadelphia's annual spring food festival called Book and the Cook (created by White Dog Café owner Judy Wicks) has done much to bring national attention to the City of Brotherly Love. Unlike New Orleans, which depends primarily on tourism for its restaurant business, Philadelphia's success story has been the result of a grassroots appreciation of good food paired with its old loyalty to farm markets and regional produce.

The anomaly for the entire region is Washington, D.C., which for its first century was largely an artificial city carved out of Maryland farmland. Aside from the White House, where lavish dinners were *de rigueur*—but not under every administration—Washington was a boardinghouse town for congressmen and not noted for its good food. By the early 1900s, the city evolved into a more cosmopolitan place, yet retained a provincial Southern character well into the 1960s, when the Kennedys brought a new kind of flair to the capital, and George-

town and northwest Washington underwent a cultural revitalization. However, there were always a few popular restaurants, such as Marjorie Hendrick's Watergate Inn, which served regional American specialties, even a respectable Pennsylvania Dutch menu. More recently, the influx of Vietnamese immigrants and the renovation of numerous downtown buildings have led to an exciting new mix of culinary choices.

## THE MIDWEST

The term “Midwest” first appeared in print in 1880 to describe the Kansas-Nebraska region and was enlarged by 1910 to include all twelve of what are now considered the midwestern states: Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin. Geographic features of what are now considered the midwestern states include wide and fertile river valleys, limestone bluffs overlooking rivers and lakes, broad expanses of grasslands, the Great Lakes, the dry and rocky Badlands of the Dakotas, the deciduous woodlands of the northern Midwest and southern Missouri, the sandhills of Nebraska, and wetlands.

According to the geographer James R. Shortridge, “midwestern” connotes pastoralism, small town life, hospitality and friendliness, traditional values, farmers, yeoman society, and the Jeffersonian ideal. “The Midwest is America’s pastoral face,” he says, “etched into our consciousness as a permanent physical location, despite the presence of industrial cities” (Fertig, 1999, p. 30).

The most prominent geographic feature of the Midwest is rolling grassland or prairie. But of the 400,000 square miles of prairie that once stretched from central Ohio westward to the foothills of the Colorado Rockies and from Alberta, Manitoba, and Saskatchewan in Canada south to central Texas, less than 1 percent has remained natural prairie (Fertig, 1999, p. 166).

### Native Foods

Before European settlement of the Midwest, Native American tribes gathered wild foods, such as native persimmons, papaws, berries, nuts of all kinds, and prairie turnips (Wilson, 1987, p. 119). Wild rice, really an aquatic grass, not a true rice, is the only grain native to North America, and it was a staple food of the Sioux and

Chippewa tribes. Wild rice grows in the lakes and rivers of Minnesota, upper Michigan, northern Wisconsin, and lower Canada (Fertig, 1999, p. 223).

Wild game included venison, rabbit, elk, antelope, quail, migrating geese and ducks, prairie chickens, wild turkeys, and the American buffalo (bison). Certain tribes also planted many different varieties of corn, beans, squash, and sunflowers (Wilson, 1987, pp. 16, 58, 68, 82–84). Dakota Sioux Indians pounded buffalo fat, dried meat, parched cornmeal, and dried berries together to make “wasna,” a high-calorie trail food (Episcopal Church Women, 1991, vol. 2, p. 21). Native Americans also fished for walleyed pike, bass, and perch from the lakes and catfish and trout from the rivers and streams.

Most of the prairie ultimately became productive farmland, small towns, cities, and suburbs. It is rangeland to the American cattle industry and is recognized as the nation’s breadbasket. The eastern or short-grass prairie in Ohio, Indiana, Illinois, and Iowa has become the corn belt. The western or tall-grass prairie in Kansas, Nebraska, the Dakotas, and Canada has become the wheat belt. The central mixed-grass prairie in the hilly grasslands of southern Indiana, Illinois, and southwestern Wisconsin has become the dairy belt (Fertig, 1999, p. xi).

### Midwestern Cooking

Midwestern cooking reflects both the bounty of the land and the ethnic diversity of the population. Favorites include wheat and honey buns, kolaches (fruit-filled sweet yeast dough pastries, originally *kolače*), traditional breads of all kinds, steaks, hamburgers, fried chicken, and pot roast. Locally brewed wheat beers are enlivened with a squeeze of lemon and accompany a bowl of chuck wagon chili zipped with the heat of peppers. Crisply roasted pheasant and other game delicacies are autumn treats. A piece of homemade pie and a cup of coffee welcome a newcomer, provide a warm and homey occasion for catching up with all the gossip, or bring a sweet ending to a family dinner.

City dwellers start the day with a cup of coffee and a bagel or a piece of toast. For farm families a hearty breakfast of bacon or sausage, eggs, biscuits or toast, and hash browns is more common. Lunch is a sandwich or salad and soup, perhaps a favorite bean soup. For dinner farm families might enjoy a slow-simmered pot roast or stew that has cooked all day. Midwesterners are also fond of casseroles, known as “hot dishes” in Minnesota, that can be assembled early in the day and baked later on. City households might have pasta, grilled chicken, or steak.

From barbecue competitions in the warmer months to ethnic food festivals throughout the year, midwesterners proudly affirm their culinary traditions. Residents of Milwaukee, Wisconsin, enjoy traditional Friday night fish fries at restaurants and churches. Catholic churches in rural parts of eastern Indiana and western Ohio offer chicken dinners throughout the summer and fall months,

Main Dining Room looking west, as seen from the balcony of Private Dining Room "B." Avenue of Palma is to the left; the windows to the right overlook Lake Shore Drive and Lake Michigan.

featuring chicken fried in lard, garden vegetables, and homemade pies and cakes. The Door County Fish Boil is an ongoing summer ritual in Wisconsin in which whitefish, potatoes, and onions are boiled to overflowing in an outdoor cauldron.

### Culinary Traditions

During the late 1700s and early 1800s settlers from the original thirteen American colonies began to move westward into Ohio, Indiana, Illinois, and Michigan. French settlers had already established villages along the Mississippi River in what is now Illinois, Missouri, and Iowa, and along the Missouri River in what is now Missouri and Kansas. These small settlements began to grow as the Louisiana Purchase, acquired by President Thomas Jefferson in 1803, opened up vast tracts of land for settlement. Between 1865 and 1880 Kansas attracted more immigrants than any other place in the nation. The promise of virtually free land and a chance to start over drew thousands to the rolling prairie. The first Homestead Act, passed by Congress in 1862, enabled the head of a family to claim 160 acres of land in Kansas for only a small filing fee and a residency requirement of five years (Fertig, 1999, p. 29).

As the Homestead Acts continued to be revised, new land was opened up in North and South Dakota, Iowa, and Nebraska that attracted new groups of immigrants, including Poles, Irish, Czechs or Bohemians, and Austrians. Each adult in the family could claim 160 acres, up to 480 acres per family, on the prairie. For a small filing fee the families could farm the land providing they built a homestead and lived there for a certain number of months a year. Women as well as men filed claims and lived on the land until it was theirs after the residency requirement had been completed (Fertig, 1999, p. 29). Each ethnic group brought its own unique culinary traditions to the melting pot of the Midwest.

**Czech.** Immigrants from what became Czechoslovakia brought their love of sweet and sour flavors, dumplings of all kinds, dried fruits and mushrooms, and kolache. Wild duck or jackrabbit was marinated in a vinegar and spice mixture, then roasted in the oven. The gravy was thickened with sour cream. Dumplings made from flour, bread crumbs, or potatoes were cooked on top of simmering stews or soups. Dried fruits and mushrooms were plumped in liquid and made into sweet or savory soups. Barley filled out stuffed cabbages or added depth to wild

The Midwest is home to numerous ethnic communities. One of the largest is the Polish community in Chicago and around Detroit. Polish foods are available in many parts of the Midwest, and the best known are *pierogi*. PHOTO BY ANDRÉ BARANOWSKI.

mushrooms in a baked dish. Cold weather vegetables like cabbage, carrots, potatoes, and parsnips also feature in Czech cooking. Kolache, tiny individual coffeecakes made of buttery yeast dough and filled with fruit butters or preserves, are a favorite fresh and hot in Nebraska, South Dakota, and Kansas kitchens.

**German.** The Heartland welcomed Germans from many different culinary traditions, and each group brought a different cooking style. The Volga Germans enjoyed a tradition of *bierocks*, *verenicke*, and other dishes similar to those of the Russian Mennonites. The “border people” from Bavaria loved homemade noodles and sweet-sour dishes, such as sweet-sour heart, liver, and tongue. Most of their cuisine was centered around cabbage and pork of all kinds. Smoky flavors combined with sweet and sour flavors, and onions and herbs. Homemade sauerkraut simmered with pork, potato pancakes, tortes, braised cabbage, sausage cooked in beer, honey, and spice cookies entered mainstream American cuisine thanks to German immigrants.

**Russian Mennonite.** Wheat-farming Russian Mennonites, who brought the first Turkey red winter wheat seeds to Kansas in 1875, are credited with transforming this part of the prairie into the nation’s breadbasket (Fertig, 1998, pp. 47–57). Their foodways were influenced by so-

journs in the Netherlands, Germany, and the Ukraine. A Protestant sect advocating a simple life and a firm commitment to the ideas of the church, much like the Amish, the Mennonites kept searching for a place where they could work and worship in peace. Fleeing religious persecution for their pacifist views, the Mennonites brought their favorite foodways with them to each new homeland. One specialty, a fruit soup or *moos* (pronounced “mose”), is thickened with flour. *Verenicke*, a ravioli-like pasta filled with dry-curd cheese, is served with sour cream ham gravy, jelly, or syrup. Homemade bread is a staple in most households, but the traditional favorite is *zwieback*, a brioche-type sweet yeast bread often served on Sundays. When sliced and toasted in the oven, it takes on a nutty, delicious flavor and keeps for weeks. Immigrant families often brought baskets of toasted *zwieback* to last until they reached the prairie.

**Swedish.** Pure, clean flavors combine with rich, buttery baked goods and creamy, mild tastes to form the constellation of Swedish foods of the Midwest. The flavors and colors of *sillsalat*, pickled herring, and pickled beets offer a taste counterpoint to the mild flavors of Swedish potato sausage, baked brown beans, and Swedish yellow pea soup. Fresh dill turns up in potato dishes and pickles of all kinds. But the highlight of a meal is always the baked goods: hard and crispy *knackebrod* with soup, almond-flavored *kringler* or saffron-flavored Lucia buns (for Saint Lucia Day on 14 December) and tea rings with breakfast, mellow *limpa* rye bread with dinner. Mellow and milky desserts like *ostakaka* and rice pudding are often served with a red fruit sauce as much for a color contrast as for a taste complement. Indeed deep red is a favorite punctuation mark in Swedish meals, whether it appears in the spiced *gluhwein* on special occasions, beet dishes and *sillsalat*, or lingonberry and red currant sauces for everything from lacy Swedish pancakes to roast goose.

**Polish.** Without the traditional “seven sours” of pickled vegetables, no deluxe Polish meal would be complete. Centered around hearty peasant food, the cooking of Poland is full of thick soups, dried mushrooms, sauerkraut, potatoes, ground and spiced meats, fish with horseradish sauce, sour rye bread, and buttery baked goods. The Easter tradition of “breakfast all day long” and the Christmas tradition of the multicourse *Vigilia* hold firm in Polish families. Sour cream, vinegar, plums, horseradish, beets, cabbage, potatoes, poppy seeds, caraway seeds, and allspice configure and reconfigure in countless recipes. Buttery baked goods flavored with almonds and poppy seeds, smoked sausages of all kinds, poached pike with horseradish sauce, marzipan baked apples, and hering in sour cream reflect the diversity of this cuisine.

**Italian.** Italians, mainly from Sicily, were one of the last immigrant groups to arrive in the Midwest, in the early 1900s. Many Italian immigrants became market gardeners or opened restaurants or produce businesses in places

like Des Moines, Chicago, St. Louis, Cincinnati, and Kansas City. Varieties of Italian cookies, some made with pine nuts or fig preserves, star in Italian bakeries and festivals throughout the Heartland. *Amogio*, a marinade of white wine, garlic, and herbs, flavors chicken and beef, which is then rolled in *modiga* or flavored breadcrumbs and grilled. Zesty tomato sauce tops pasta dishes and baked eggplant.

**Barbecue.** Traveling up from South America, the barbecue tradition is rooted in the foodways of rain-forest Indians, who smoked meats over green wood to preserve them for later use. Over time this technique spread to the American South and from there to Missouri, where black residents used pit barbecues to smoke lesser and cheaper cuts of meat like spareribs and brisket. In 1916 the Kansas City resident Henry Perry began selling barbecued turkey, duck, pig, and goose, and by 1929 he had three separate barbecue stands. His fame spread, and he taught others, including Charlie Bryant, the secrets of slow smoking. Bryant and his brother Arthur Bryant eventually took over Perry's business, calling it Charlie Bryant's. When Charlie died in 1952, it became Arthur Bryant's, whose barbecue rose to fame when Calvin Trillin extolled it. By the early twenty-first century Kansas City had over one hundred barbecue joints, from the basic shack to the high-style restaurant (Stein and Davis, 1985, pp. 11–20).

### State Fairs

The region's agricultural roots are celebrated every year in state fairs held in late summer and early fall. During the 1850s, when the region was predominately agricultural, state fairs were established throughout the Midwest. The first was the Ohio State Fair, held in Cincinnati in 1850. Even though most state economies changed from mainly agricultural to businesses of other kinds, the tradition continued into the twenty-first century. They usually include the butter cow or other object or person sculpted from butter, a traditional attraction that began at the Ohio State Fair in 1903. Concessions offer unique state fair food, such as pork chop dinners in Iowa, barbecued rib dinners in Missouri, fried chicken dinners in Ohio, Indian tacos in Nebraska, and anything you want on a stick, including cheese, bamboo beef, smoked turkey legs, roasted corn, and corn dogs (Fertig, 1999, p. 60).

## NEW ENGLAND

New England's early foodways set a pattern for the common, everyday cookery that would be carried across the American continent and endure through time to the present. Many dishes considered today particularly American—pumpkin pie, johnnycake, pork and baked beans, apple pie, among others—evolved in New England from the yeoman English cookery of the seventeenth century colonist who came to the region.

### Early Preferences

English settlers arrived in New England with a decided preference for beef and beer, wheat bread, peas and root vegetables, tree fruits, particularly apple, and well-developed dairying practices. Their seasoning habits were close to the rich and complex flavorings of the late medieval era. They ate fish on fast days, regarded it appropriately as light fare, but often associated it, especially salted fish, with poverty. Venison hunting and consumption was, for these people, restricted in Old England as sport and fare for the gentry. Within a few decades, settlers had considerably altered some of these habits to accommodate the climate and growing conditions of their new home, the variable supplies of still-developing trade networks, and economic realities of a colony as a joint stock company.

### Climate and Cash Flow

New England's weather was much colder, particularly in winter, than the English were accustomed to in the Gulf Stream-moderated British Isles. The colonial period and early nineteenth century were, as well, affected by what weather historians have characterized as a mini ice age. Still summers were shorter, hotter, and more humid than English growing seasons, conditions that adversely affected wheat and pea growing in particular. A recurring mildew attacked wheat, gradually impelling a switch from wheat flour bread to one made with rye and the Native American's cornmeal, which settlers named "Indian" to produce a loaf called "rye and Indian." New England's climate favored the native beans that ultimately fared better than peas as a field crop and helped urge the shift to the beans pottage that would evolve into baked beans.

New England's climate limited natural abundance. Compared to other colonies in North America, settlers in the north were limited to gathering greens in early spring,

The icon food of New England is baked beans—one of Boston's nicknames is "Beantown"—and many families pride themselves on heirloom recipes, some tracing to the 1600s. Baked beans were originally prepared in earthenware cookpots. Slow simmering is one of the cooking secrets for a successful recipe.

and wild fruits and nuts in two to three months of summer and early fall. Deer, moose, and small animals were most toothsome in the fall before they had spent cold months grazing on evergreens and mosses. Settlers near water could hunt wild fowl, as well as catch fish. But cold weather hunting and fishing was often strenuous and yielded uncertain results with at least as great an expenditure of energy finding food as would be gained from eating it. Besides the issue of dubious food value, early settlers viewed hunting and gathering as the sport of the gentry and idle, and, more to the point, they faced economic realities which mitigated against that activity.

Of first importance was establishing an economic base for the colonies settled all through southern New England. As joint stock companies, they owed money, and much effort was expended to raise it and to create some business that would yield profit. From the start, this impulse created a market economy that skewed settlers' activity toward lumbering, fishing, and producing the most merchantable crops and agricultural products, and away from growing experimental foodstuffs or from indulging in hunting and gathering with potentially unreliable results. New England's gentry farmers in later years took up the gentlemanly farming found earlier in the South and the Middle Atlantic colonies, growing experimental crops, vegetables, conducting animal husbandry, and cultivating fruit trees—quince, pears, cherries, apricots, and even peaches, but chiefly apples. By the later nineteenth century even middle-class professionals spent their leisure growing everything from strawberries to pumpkins in gentle competition, but for the first century and anywhere on New England's frontiers, Yankees

preferred the tried, true, and reliably abundant. This conservatism in taste and preference for reliability endured through the centuries.

### Food from the Native Americans

New England's settlers adopted a limited range of food stuff and agricultural practice from the Native Americans. As most cultures do when encountering new foods, the English accepted those that most resembled the familiar and preferred. Practicality drove the adoption of what the Native Americans called the Three Sisters: corn, squash and pumpkins, and beans.

Corn grew and yielded well. Cornmeal behaved culinarily like the familiar oatmeal and was handled as oatmeal had been in England in the unleavened bread bannock. Bannock was also known in the North of England as jonniken. The corruption of the term jonniken accounts for the name johnnycake, best seen in the Rhode Island spelling of jonnycake, which is to this day an unleavened mixture of cornmeal, salt, water, sometimes thinned with milk, and baked over fire on a flat pan in traditional bannock fashion. Cornmeal was also cooked as a mush or hasty pudding, as had been oatmeal. Similarly, Indian meal was used in place of the customary coarse oatmeal to make the milk-based, molasses-sweetened Indian pudding, ultimately named for the cornmeal used to make it.

Squash and pumpkins worked in recipes like apples did, so they were stewed as a sauce or sliced in pie form as apples were in the seventeenth century. Later, in the eighteenth century, they would be used like the similarly textured sweet potato in the sweet puddings often baked in pastry shells, and thus gradually evolved into pumpkin pie.

For many centuries, the most commonly used bean in Europe was a large flat bean of which the modern fava is a kind. Settlers encountered the smaller, rounder, kidney-shaped beans of North America that could be used as peas had always been used in potages and soups, often with salted meat, or even sometimes ground to be combined with grains for a coarse bread. Most of the early potages were stewed dishes, but toward the end of the eighteenth century, New Englanders took advantage of still warm brick bake ovens to bake slowly a pot full of beans with salt pork. Baked beans were barely sweetened in the early era, the most usual proportion being one large spoonful of molasses to a quart of dried beans. Industrially produced beans of the later nineteenth and early twentieth centuries were notoriously and popularly sweet, and many homemakers followed the example to create the sweet baked beans we know today.

### Reform and Beer and Bread

Uncertainty with grain crops together with the relative ease of apple growing gradually brought about a slight shift from beer and ale to apple cider drinking. Still for the first two centuries of New England's history, housewives continued the paired activities of baking and brew-

ing, both of which used and generated yeast. The advent of the Temperance movement, the earliest of the foodways-related reforms to take hold of New England, gradually eliminated brewed beverages from widespread daily and family consumption and replaced them with tea and coffee, and eventually for festive occasions, lemonade. Some people continued to drink wine, and beer and cider, but the Temperance influence was widespread in New England, and broke the bread-making and brewing connection, opening the way for commercial yeast-making and the wider acceptance and manufacture of chemical leavenings such as pearlash, later saleratus, and eventually baking soda and cream of tartar, and baking powder.

New Englanders reverted to making bread with wheat after the Eire Canal opened in the 1820s, and lower cost wheat flour came on the market. The old rye-and-Indian gradually disappeared, but in the mid-nineteenth century the combination could be found in Boston brown bread, which continued to use rye, cornmeal, and sometimes wheat flour as well, mixed with chemical leavenings, milk, sweetened with molasses, and steamed—more pudding than bread, but eaten as bread would be, often accompanying baked pork and beans. This combination continues even to our time, and was carried across the country anywhere New Englanders settled.

### Fish, Molasses, and Industry

New England was the earliest region to industrialize. In the late eighteenth and early nineteenth centuries, Boston and Providence capitalists converted money from trade and shipping into textile manufacture. Some of this wealth had been originally generated by the salt cod trade with Europe and the West Indies, where it formed a leg of the well-known triangle trade that included molasses and slaves. Settlers engaged in cod fishing early, utilizing one of the regions natural resources, in order to produce an income for repayment of investments in colonies. The codfish that hangs in the Massachusetts State House has little to do with gastronomic preferences of New Englanders, but honors instead the source of much wealth.

New Englanders certainly did consume salt codfish, often on Saturday, often in the form of a boiled dinner with root vegetables, and a sauce of fried salt pork or butter and chopped boiled eggs. This dish gained the derisive nickname Cape Cod Turkey, variously Block Island Turkey. Chowder, another dish with strong New England associations, came ashore from the fishing fleets. Earliest versions of it were comprised of fishermen's provisions, salt pork and hardtack, to which fish was added. When Yankees added potatoes to their everyday diet, they were used in the chowder, too, eventually replacing hardtack as a thickener.

The molasses was made into rum, and provided an inexpensive sweetening characteristic of many of New England's early dishes. Wherever saltwater access made

The Maine lobster dinner is one of New England's most popular tourist attractions. The menu may vary from restaurant to restaurant, but the basics are universal: boiled lobster, corn on the cob, cornbread, and coleslaw. Many menus include oysters or quahogs (a type of clam) for starters. © BOB KRIST/CORBIS.

shipping possible molasses, brown sugar, and refined white sugar were available to cooks, even in the hinterlands. Two other sweeteners, commonplace in interior New England, were a thick, molasses-like syrup made from boiled down sweet apple cider, and maple sugar. Produced mostly as a commodity, partly for home consumption, sugar-making from maple tree sap became a widespread activity in the middle to late eighteenth century, and grew steadily through the nineteenth. The goal was sugar production, though in more recent times, the syrup has become more desirable.

The industrialization of New England promoted urban growth and transformed many New Englanders from food producers to food consumers only. Urbanization created a stronger market for dairy products—cheese, milk, and butter—and changed many New England farms from producing varied crops to focusing on a specialty such as dairying, orchards, or raising poultry for meat and eggs. By the mid-nineteenth century, grain and even beef and pork were brought into New England's cities from the West by way of railroads and artificial refrigeration.

New England has many distinctive cookeries, from the shipboard fare of the old whaling ships to the rustic cookery of Maine logging camps. This cook in the Fletcher Field Logging Camp (Washington County, Maine) is shown preparing bread in a 1948 photograph taken by Leland J. Prater. © CORBIS.

Factory work also changed the daily patterns of meals for many New Englanders. The old rural pattern of a morning breakfast, noon dinner, and a smaller meal called tea or supper in the evening gave way to breakfast, a lunch carried to work, and a supper or dinner in the evening at the end of the work day. For many laboring families, however, dinner became a Sunday phenomenon, placed in the middle of the day. People in farming communities would continue the old pattern well into the twentieth century.

### Immigration

Industrialization encouraged immigration from the French Canadian north and Europe and gradually introduced ethnic flavors to the region. The same reformist impulse that gave Temperance such a strong footing in New England also worked toward mainstreaming the newcomers' diets. Scientific cooking and cooking schools, such as the well-known Boston Cooking School, made as their missions both to educate middle-class women in healthful and aesthetically pleasing cookery, but also to

uplift the poor, often immigrant, populations caught in the economic vicissitudes of industrialization. This combined readily with many immigrants' desire to meld into American life, which they accomplished by giving up some of their traditional dishes to eat more meat. Many ethnic groups living in neighborhoods nevertheless managed to continue many familiar foodways and supported local groceries, butchers, fish markets, and green grocers. In the twentieth century, with the culmination of nearly a century of exposure to Italians, Portuguese, Eastern Europeans, French, and Asians, Yankee cooks ate in ethnic restaurants and experimented with foreign dishes at home.

### Thanksgiving

The national holiday Thanksgiving owes its origins to the sustained custom of autumn harvest festivals brought to and continued in New England. Originally a moveable feast that could occur almost anytime at the conclusion of the growing season, early New Englanders preferred to conclude butchering season before celebrating the

harvest, usually at the end of November or beginning of December. Individual colonial, later state, governors declared what day, usually a Thursday, the holiday would be observed. A holiday of family reunion, feasting, and recreation, Thanksgiving's menu has been much mythologized, starting with the event considered the first Thanksgiving, described by Edward Winslow in *Mourt's Relation*: "so we might after a special manner rejoice together after we had gathered the fruit of our Labors." Winslow reported that they had wild fowl and venison, and William Bradford writing in *Of Plimoth Plantation* about the same event, referred to fish, turkeys, and Indian meal.

In the nineteenth century when the story of founding settlers of Plymouth was romanticized, the association of turkeys and the so-called Pilgrims at Thanksgiving assured that dish would appear on the table along with roast pork, chicken pies, fall-harvested vegetables such as squash, potatoes, and turnips. Cranberry sauce and pickles and other preserves accompanied the meal, and pies followed made of pumpkin, apple, and mincemeat. This menu, with very few substantial changes, spread across the country with settlers, and has continued to the present along with the habit of observing the day. While nearly every state in the nation observed Thanksgiving in some form, the day became a nationally declared holiday when Abraham Lincoln, at the urging of Sarah Josepha Hale, set the holiday at the last Thursday in November. Franklin Roosevelt changed the date to the fourth Thursday, where it rests today.

### PENNSYLVANIA DUTCH FOOD

Also referred to as Pennsylvania German and incorrectly as Amish, this rural style of regional American cookery underwent its greatest flowering during the nineteenth century. It became one of the primary regional cookeries of the Middle Atlantic and Midwestern states, encompassing communities scattered throughout Pennsylvania, Maryland, Virginia, North Carolina, Ohio, Indiana, Illinois, Iowa, and Wisconsin, and of Ontario, Canada. Each area of settlement developed its own regional specialties or regional interpretation of shared culinary themes. The heartland of the cookery, however, is southeastern Pennsylvania, where it first evolved in the eighteenth and early nineteenth centuries. Because they represent a composite of several German-speaking cultures that settled in colonial America, Pennsylvania Dutch foods and foodways are remarkably diverse, incorporating elements of Swiss, Southwest German, and North German cuisines but transformed into something essentially American.

If a unifying thread once existed, it was in characteristics shared with the regional cookery of Alsace, France, as exemplified by the cookery books of George Girardey (1842) and William Vollmer (1856). The differences between Alsatian and Pennsylvania Dutch cuisines are much more acute, since a large number of the Pennsylvania Dutch shifted from daily wine consumption before the Civil War to near total abstinence. Wine was replaced by sugar, especially in the tourist fare styled as Amish or Pennsylvania Dutch. Also opinions vary over what to call this ethnic cookery, reflecting an evolution both of the group's self-perceptions and how it is seen by outsiders.

The term "Pennsylvania Dutch," the oldest label, derived from the colloquial English use of "Dutch" to designate anyone from the Rhine Valley, be they Hollanders, Germans, or Swiss. Even William Shakespeare used the word in this sense. The term was given popular currency by the travel writer Phebe Earle Gibbons in *Pennsylvania Dutch and Other Essays* (1872). One body of American scholars who study this culture prefers the term "Pennsylvania Dutch" since it implies a native hybrid that

Fish mold for the New Year. Berks County, Pennsylvania, circa 1810. Yellow glaze on pale earthenware. This ancient symbol of the New Year traces to the sacred salmon of the Rhineland Celts, which swam into the Rhine in vast numbers in early March (old New Year). By chasing its tail, the fish is symbolically chasing the old year, since its head represents the new. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

evolved in North America as opposed to German American cuisine. An opposing body prefers to use the term “Pennsylvania German,” a label that came into vogue during the 1890s among a group of scholars, mostly Germanophiles, who viewed the culture as a pure, uncreolized European transplant. These two opposing points of view, an American-centered definition and cultural vision defined by Europe, remained in tension into the twenty-first century.

With the ascendancy of Adolf Hitler in the 1930s, the term “Pennsylvania German” fell into disfavor due to anti-German sentiments in the United States. This shift was exemplified by J. George Frederick’s *Pennsylvania Dutch and Their Cookery* (1935), which struck a patriotic note by highlighting famous individuals from the culture and the very Americanness of the cuisine. At the same time the Amish Mennonites, whose agrarian lifestyle represents a co-mingling of Old and New World themes and whose pacifist beliefs were fully opposite to those espoused by Hitler, provided a new and convenient symbol for the culture as a whole. Numerically, at the end of the twentieth century the Amish represented less than 5 percent of the total Pennsylvania Dutch population, yet tourism after the late 1940s exploited them to such an extent that “Amish” became a muddled synonym for both “Pennsylvania Dutch” and “Pennsylvania German.”

A stylized and highly limited menu format created by the Pennsylvania Dutch Folk Festival at Kutztown, Pennsylvania, and its many spin-offs during the early

1950s led to a canonized cuisine, including chow-chow pickles, whoopie pies, chicken corn soup, and red velvet cake, that most restaurants claim is Dutch. The foods on this limited menu neglect the wide range of cooking styles prevalent in the community, emphasizing only peasant roots or once-popular Victorian farm fare, cracker pudding for example, at the expense of the more sophisticated ethnic dishes. The term “Amish” is also commonly misapplied to this menu and serves as an advertising gimmick for such dubious products as Amish Polish pickles, Amish tortillas, or Amish friendship bread. The implication is that, since the Amish live close to the land, foods associated with them convey values of purity, integrity, simplicity, and homemade goodness, commercial connotations formerly associated with the term “Quaker” in the nineteenth century. Thus the Amish theme has given rise not only to a type of interior decoration (the Amish are forbidden to decorate their homes) but also to a spate of Amish-style cookbooks promoting those values.

Historically, the best Pennsylvania Dutch cooks and cookbook authors, like Mrs. J. A. Keller, Edith Bertels Thomas, Ruth Hutchison, Ann Hark, John Levan, and Preston Barba, came from the ranks of the mainstream groups, such as the Lutherans, Reformed, or Moravian.

### GINGERKRAUT (*IMBERGRAUT*)

This is a Christmas dish generally eaten with turkey or roast goose. It is also served at New Year’s.

Yield: 6 to 8 servings

- ¼ cup (60 ml) walnut oil (olive oil may be substituted)
- 2 Tablespoons (15 g) white mustard seed
- 2 medium onions (300 g), sliced
- 2 cups (500 ml) turkey or chicken stock
- 2 pounds (1 kg) sauerkraut, drained of liquid
- 3 Tablespoons (50 g) coarsely shredded fresh ginger root
- 15 juniper berries
- 3 Tablespoons (15 g) chopped red bell pepper

Heat the oil in a deep nonreactive saucepan. Add the mustard seed and sizzle until they pop and begin to turn gray (about 1 minute). Add the sliced onions and cover. Let the onions sweat for 10 minutes, then add the turkey or chicken stock, sauerkraut, ginger, and juniper berries. Cover and simmer over a low heat for 1 hour. Add the chopped pepper as a garnish and serve immediately.

SOURCE: Weaver, *Pennsylvania Dutch Country Cooking*, p. 174

Professionals from that segment of the community operated the inns, the once-numerous wineries, the hotels, the bakeries, and the confectionery shops. The plain sects, like the Amish, were the farmers who provided the cuisine with high-quality, fresh materials, keeping alive a system of farm markets that survived into the twenty-first century. But due to their religious restrictions, they could not indulge in fine cookery, such as goose liver pie or wine noodles, of the sort taught in Moravian girls' schools. This dichotomy of cuisines based on differences in income and religion is perhaps best exemplified by Moravian sugar cake, a rich pastry served with coffee, and the various kinds of *Botboi* (potpie) eaten by farmers for Sunday dinner. Both dishes are of medieval origin.

Moravian sugar cake is a festive bread sweetened with brown sugar and cinnamon. It originally was baked in large, round loaves that were broken apart and served during Moravian love feasts, a congregational celebration. The *Botboi* (pronounced BOT-boy), originally an English colonial one-pot meal boiled in an iron pot lined with dough, gradually evolved a Pennsylvania Dutch identity by replacing the dough, which the English made with suet, with flat egg noodles. The concept of layering ingredients between noodles, similar to lasagna, traces to classical antiquity and may represent a technique preserved in the medieval cookeries of southern Germany and Alsace. In any case, *Botboi* further evolved among the Pennsylvania Dutch so that each Pennsylvania region could claim its own identifying dish, such as the chicken-and-saffron *Botboi* of Lancaster and Lebanon Counties, the pea *Botboi* of the Cumberland Valley, and the peach *Botboi* of Somerset County.

Other types of Pennsylvania Dutch dishes include the *Schales* (pronounced SHAH-less), a species of baked casserole normally made with legumes and shredded vegetables; the *Gumbis* (pronounced GOOM-biss), a deep-dish casserole consisting of layered ingredients; and various distinctive types of meat dishes and sausages. The most popular form of *Gumbis* is a dish called *Schnitz-un-Gnepp* (pronounced SHNITS-oon-NEPP), a baked or stewed mixture of dried apples, ham, and dumplings. Among the meat dishes, *Panbas* (pronounced PAN-haas), a word derived from ancient Belgic *pannas*, is sold in most farm markets as a breakfast dish. The word "scrapple" is replacing the dialect name *Panbas*. Of Lower Rhineland origin, *Panbas* was eaten as a porridge on butchering day but became a pot pudding, made with the leftovers of pork butchering, that is sliced, fried, and eaten with a variety of condiments. The primary thickeners are buckwheat and cornmeal.

Among the Pennsylvania Dutch, *Seimawe* (pronounced ZEI-maa-eh) is considered a "national" dish. A pork stomach is stuffed with potatoes, sausage, bread, and various herbs, poached, then baked. Served with great fanfare, the best are those that can be sliced like sausage. The origin of this dish is quite ancient and probably traces to pre-Germanic cultures in the Rhineland. Other

Broadside print for Adam and Eve Day (December 24), an old Pennsylvania Dutch folk observance that associated the Tree of Knowledge with the Christmas tree. Printed by Heinrich Sage, Reading, Pennsylvania, circa 1820. ROUGHWOOD COLLECTION.

signature foods are sauerkraut, de rigueur for New Year's dinner; summer sausage, also called Lebanon bologna; and shoofly pie, a molasses crumb cake baked in a pie shell that was first introduced commercially at the U.S. centennial in 1876. Of all the Pennsylvania Dutch contributions to American culture at large, the most lasting have been the Christmas panoply of gingerbreads, candies, and pastries; pretzels of all kinds; and vegetable gardening, which has persisted as a symbol of biodiversity and small-scale sustainable agriculture.

## PIONEER FOOD

Pioneer foods can be defined as the emergency foods and the makeshift methods of food preparation employed by European settlers in the Americas, Africa, Australia, and other parts of the world to which European culture was transplanted en masse. While work has been done on such scattered themes as the Australian Germans (Heuzenroeder, 2001), the German settlers on the Russian steppes (Kloberdanz and Kloberdanz, 1993), and the Portuguese experience in Brazil (Camara Cascudo, 1967), research on pioneer cultures has largely concentrated on particular ethnic groups rather than looking at overall patterns and themes. This essay attempts to outline some general observations on the pioneer food culture of the continental United States. These foods have played an important role as symbols in traditional culture and as continuing images in modern mass culture. The Fort restaurant outside of Denver has become a national symbol of this genre of cookery, and its owner, Samuel Arnold, has been a keen supporter of research on this subject. Jacqueline Williams's *Wagon Wheel Kitchens* (1993) is especially noteworthy for its treatment of pioneer foods along the Oregon Trail.

Faced with the double problem of establishing new economic and social communities to replace the ones left behind, early American settlers were forced to make compromises on what they served on their tables. The primitive, log-cabin-in-the-clearing style of life was indeed rugged and different from later stages of more settled food production and consumption. In wooded areas fields had to be cleared before farming and gardening could commence. European methods of slash-and-burn agriculture were employed to make new ground amid the stumps of trees later removed. On the Great Plains the log cabin became the sod house, but on all frontiers the initial dependence was significantly on wild foods to supplement the diet. This included game, such as wild turkey, jackrabbit, quail, pigeon, venison, squirrel, groundhog, bear, and, of course, buffalo.

County histories are rich in stories of pioneer foodways, especially in noting wild plant foods that are no longer consumed. Cattail flapjacks, the wapato or swamp potato (*Sagittaria latifolia*), prairie breadroot (*Psoralea esculenta*), the pond apple (*Annona glabra*) of Florida, the buffalo pea (*Astragalus crassicaepus*), the cabbage palm

(*Sabal palmetto*) of the coastal South, and the miner's lettuce (*Montia perfoliata*) of the West Coast all carry names that allude to their substitute uses in settlers' diets. Some native plants, like miner's lettuce and Mormon tea (*Ephedra viridis*), are still widely consumed in the twenty-first century, while others, like the mayhaw (*Crataegus aestivalis*) of the Deep South, have become symbols of regional cooking (mayhaw jelly). Many wild food plants, like camass (*Comassia quamash*) of the Northwest, are grown mostly as garden ornamentals.

Aside from wild plants, the principal food source derived from the Native Americans was corn (maize), which became the primary grain raised by backwoods farmers, taking precedence over wheat and other cash crops. Corn products eaten at the pioneer table were many. Corn on the cob was a favorite summer dish once corn attained the milk stage in midsummer. It was commonly roasted in ashes downhearth rather than boiled. In fact, in the twenty-first century is still called "roasting ears" in many parts of Appalachia.

Cornmeal mush or suppawn was a common winter dish normally eaten with milk or syrup. The solidified residue was sliced and fried the next day for breakfast. Dried corn was also a winter dish, along with hominy or samp. The latter was of two kinds: large hominy hulled in lye water, then boiled and served whole; or small hominy (grits), which was ground to create several grades of texture, depending in part on the type of corn used. Small hominy is a popular dish in the South, although it was once widely eaten in other parts of the country.

Another pioneer grain, this one brought from Europe, was buckwheat, which could thrive in poor soils on hilly or mountainous land and provided bees with a local source for buckwheat honey. An English traveler through early America once referred to the ubiquitous buckwheat cake as a popular American breakfast preparation. Buckwheat was also combined with cornmeal to make various types of pork or venison scrapple known by such regional names as panhas (Pennsylvania and Ohio), poor-do (Upper South), and liver mush (Appalachia). Because of its dark color, buckwheat dishes fell out of fashion during the late nineteenth century in favor of foods made with wheat.

The prevalent method of cooking in pioneer settlements was in open fireplaces, where primitive breads, such as johnnycakes and corn dodgers, could be baked on hanging griddles or in Dutch ovens. The Dutch oven, a straight-sided iron bake kettle with a tight-fitting lid, became a symbol of frontier one-pot cooking because it could be used for baking, frying, boiling, and braising. Among the Mormon settlers of Utah, the Dutch oven represented their religious trek through the wilderness, and in the twenty-first century Dutch oven cooking remains a central feature of Mormon outdoor gatherings.

Undoubtedly the frontier diet was monotonous by any standard, especially during the winter, when greens

were few. Such was the observation of the Methodist circuit rider Marmaduke Pearce, who traveled through the thinly settled areas of western New York in 1811: "O the cold houses, the snow, the mud, the sage tea, the baked beans!" (Peck, 1860).

## THE SOUTH

One of the most popular books written about the American South, Margaret Mitchell's *Gone with the Wind* (1936), begins with a barbecue. To the 80 million people who live in the region, it would seem only appropriate. Food, like music or a syrupy drawl, has always been one of the cultural touchstones that sets the South apart.

Some of the best-known regional dishes in American cookery come from the great crescent that stretches from Virginia to eastern Texas. The South is home to a groaning table of famously down-home foods, like fried chicken, skillet cornbread, pork barbecue, pecan pie, catfish and hushpuppies, bourbon whiskey, and greens and pot likker (which refers not to real liquor but to the aromatic juices of boiled greens).

When Americans speak of the South, they usually mean the eleven states of the old Confederacy (Alabama, Arkansas, Florida, Georgia, Louisiana, Mississippi, North Carolina, South Carolina, Tennessee, Texas, and Virginia) plus parts of border states, like Kentucky and Maryland,

## ALL THE KING'S PONE

Back in the 1930s Huey Long, the pot-bellied potentate of Louisiana, tried to show his common touch by talking up the health benefits of cornbread and pot likker, a modest dish enjoyed by southerners everywhere. "The Kingfish" decreed that it was classier to dunk the bread into the likker, the savory juice left behind by boiled greens, instead of crumbling it. Julian Harris, the editor of the *Atlanta Constitution*, disagreed. Thus started the Great Corn Pone Debate of 1931.

For weeks the mock controversy raged in newspapers, as Harris accused Long of closet crumbling and Long charged Harris with yellow-corn journalism in telegrams fired off to the *Constitution's* Pot Likker and Corn Pone Department. Long even offered a jesting recipe called Pot Likker à la Dictator.

The future president Franklin D. Roosevelt eventually weighed in, proposing that the important question be referred to the 1932 Democratic National Convention. "I must admit that I crumble mine," he wrote, perhaps belying a bias from all the time he spent at the spa in Warm Springs, Georgia.

that lean toward Dixie culturally. It is a varied landscape that takes in multiple mountain ranges, a spacious swath of hill country, broad coastal plains, vast alluvial flatlands, and three thousand miles of shoreline. Historians have called it the closest thing to a nation within a nation in the United States, and it has spawned a collection of foods and foodways as varied as the landscape.

## The First Southerners

When Europeans began to arrive during the 1500s, they found the land well populated by American Indians whose ancestors had dwelled there for thousands of years. The natives fished, hunted game, gathered berries and nuts (like the indigenous pecan), and cultivated crops, especially beans, squash, and maize (corn). Early European settlers were struck by the bounty. Captain John Smith, who helped found the first permanent English colony at Jamestown, Virginia, in 1607, wrote of "an abundance of fish, lying so thicke with their heads above the water, as for want of nets . . . we attempted to catch them with a frying-pan" (quoted in Ketchum, 1964). The place-names spoke of plenty; for example, Chesapeake is an Indian word meaning "great shellfish bay."

At least one of the cornerstones of southern food was already in place when the Europeans came, that is, corn. The Powhatan tribe of Virginia showed the English how

Not the actual South, but the nostalgic South brought north and served forth in this New York club menu featuring “stimulating” Southern Comfort, fried chicken dinners (\$2.00), mint juleps, and a place to party until 4 A.M. Menu cover, 1946. ROUGHWOOD COLLECTION.

to plant, harvest, soak, and hull the native grain, which they ground into a gritty meal called rockahominy. They also made a bread of it, *appone*. Both names stuck, and southerners have enjoyed corn pone and hominy grits ever since.

Many of the foods that came to be associated with the South are not native. The Spanish, who explored the region during the 1500s and colonized Florida, introduced oranges, peaches, sugar cane, pigs, and chickens. The French, who planted their tricolor along the Gulf Coast from Mobile to New Orleans, brought their cooking techniques and used local ingredients to create new dishes like gumbo and jambalaya. The Scotch-Irish, who poured into the southern Appalachian mountains, squeezed a new distilled spirit out of corn. According to legend, a Baptist preacher by the name of Elijah Craig was the first to make bourbon whiskey in the 1780s in Bourbon County, Kentucky.

But the dominant strains of southern cooking, as of southern life, are English and African. The English who settled the region brought their own livestock and fruits (apples chief among them), a direct, earnest style of cooking, and a taste for stews, puddings, and pies.

The African slaves who were imported to work the fields starting in the 1620s brought some of the most quintessentially southern foods with them, including okra, peanuts, watermelons, and black-eyed peas. Some of these foods, peanuts, for instance, actually originated in South America but did not take root in North America until they were taken to Africa and brought back across the Atlantic in the slave trade. Slave cooks also enlivened the southern kitchen by using peppers and spices they had either known in Africa or picked up in the Caribbean, the first stop in the New World for many of them. This forced collaboration between black and white newcomers laid the foundation for the region’s cooking.

### Southern Hospitality

By the time of the American Revolution in the 1770s, the southern Atlantic colonies were developing an economic system dominated by the large-scale cultivation of single cash crops, such as tobacco and rice. The plantation system spread west after independence, as cotton bolls blanketed the region and sugar cane sprouted through the lower Mississippi River valley.

The plantations developed a reputation for lavish entertaining that led to one of the enduring legends of the young country, southern hospitality. In 1746 a correspondent for *London* magazine compared the Virginia planters’ lifestyle to that of English country squires: “All over the Colony, a universal Hospitality reigns; full Tables and open Doors, the kind Salute, the generous Detention, speak somewhat like the old Roast-beef Ages of our Forefathers. . . . Strangers are sought after with Greediness, as they pass the Country, to be invited.”

Company was so routine at Mount Vernon, George Washington’s estate, that the first president once complained in a letter that he and Martha had not dined by themselves in twenty years. The first lady evidently made a custom of large meals. The recipe for Martha Washington’s Great Cake in the files at Mount Vernon begins “Take 40 eggs.”

The apotheosis of this grand spirit was Thomas Jefferson, the third president and first epicure, who brought vanilla, macaroni, and wine making to the hills of the Virginia Piedmont. Jefferson loved to entertain at the White House and at his neoclassical mansion Monticello. His lavish entertaining was largely responsible for his dying \$40,000 in debt.

### Hard Times

Few southerners could afford to set a table like Jefferson or Washington. Before the Civil War the great majority were slaves or yeoman farmers. After the war ended slav-

ery and bankrupted the plantation system, millions became tenant farmers or sharecroppers, working fields they rented by giving landlords a large portion of what they grew.

These new American peasants were fueled by a monotonous diet of salt pork, cornbread, molasses, and whatever vegetables they were able to grow or gather. The most commonly eaten vegetables were green beans, black-eyed peas, and leafy greens (turnips in the Upper South, collards in the Lower South), usually boiled for at least an hour with ham hocks or some other pork flavoring. Sweet potatoes joined the plate in late summer, when they were harvested and stored in earthen mounds for consumption through the winter.

Humble though these foods may have been, they could summon powerful emotions among those raised on them. In Ralph Ellison's novel *Invisible Man* (1952) the narrator, a young man from the South, practically bursts into homesick tears when he smells Carolina sweet potatoes roasting at a vendor's stand on the sidewalks of New York.

Decades after the devastation of the Civil War, hunger and malnutrition lingered in the South. In the early 1900s federal doctors investigated the widespread listlessness—some called it laziness—that many had noticed among the region's poor. Much of it was blamed on pellagra, a disease of vitamin deficiency caused by a grossly unbalanced diet. Pellagra did not recede until a nutritional campaign was launched during the 1930s and cornmeal, the bulk of so many diets, was enriched with vitamin B<sub>12</sub>.

Many southern foods have long been linked with poverty. Mark Twain makes the connection in his masterpiece *The Adventures of Huckleberry Finn* (1884), when Huck tells Jim he would rather eat wheat bread because that's "what the quality eat—none of your low-down corn pone."

Indeed, southerners used to regard wheat bread as somehow elevated, calling it "light bread" to distinguish it from run-of-the-mill cornmeal. Baking with wheat did not catch on until commercially milled flour and baking powder became widely available in the late 1800s. Then southern cooks made up for lost time, making light, fluffy biscuits part of their daily routines, especially at breakfast. Kinky Friedman, a country musician from Texas, once wrote a song titled "Get Your Biscuits in the Oven and Your Buns in Bed." Most of his listeners no doubt approved of his priorities. In the South, hot bread always comes first.

### Some Special Foods

Many distinctively southern dishes are associated with special events, including holidays, family reunions, community fundraisers, and the like. On New Year's Day, for example, a peas and rice dish called hoppin' John is eaten for good luck, often with a side serving of greens to fore-

tell money. Reunions bring out cauldrons of Brunswick stew, Frogmore stew, burgoo, or muddle—hearty concoctions made in particular areas of the South with vegetables and pork, seafood, mutton, or fish respectively. Churches and athletic leagues raise money with plates of catfish and hushpuppies, fried dollops of cornmeal whose name probably derives from the way cooks used to keep dogs at bay by tossing them some batter. Funerals and homecomings produce an amazing variety of pies and cakes, a reflection of the region's pronounced sweet tooth. And some people think it would not be Christmas without ambrosia, a dessert made of grated coconut and orange sections that is virtually unseen the rest of the year.

No matter what the occasion or month, it is considered perfectly normal to accompany any meal with iced tea. Given its hot, humid climate, the South has a powerful thirst for cold beverages. Among the many soft drinks that originated in the region are the world's two most popular, Coca-Cola and Pepsi, both created by pharmacists (the first in Georgia, the latter in North Carolina) in the late 1800s.

Fried chicken, perhaps the most renowned of southern dishes, may have begun as a seasonal specialty. Its genealogy is uncertain. Among the settlers of the South, both Africans and Scots have a tradition of frying poultry. However it got there, fried chicken was already established by 1828, when Mary Randolph included a recipe for it in one of the earliest American cookbooks, *The Virginia House-wife*. She specified all the essentials, chicken parts dredged in flour, seasoned, and fried in hot fat.

In the nineteenth century fried chicken was usually eaten during the warm months, when hens hatched the chicks that grew into tender young fryers. By the mid-1900s a huge poultry industry that could supply fryers year-round had developed in Georgia, Arkansas, and the Carolinas. Poultry consumption rose throughout the calendar.

Traditionally fried chicken was a Sunday treat reserved for after-church dinners and special company, like the preacher or the in-laws. The dish gradually spread into other days of the week, spurred on by the rise of fast-food franchising after World War II. The first and largest of the chicken chains, Kentucky Fried Chicken, once advertised "Sunday dinner seven days a week." Harland Sanders, who went by the honorary title "colonel," started the business in the 1930s at a roadside cafe in Corbin, Kentucky. By the end of the twentieth century the empire that bears his goateed image was selling a taste of Dixie at nearly eleven thousand outposts around the world.

### An Enduring Love Affair

Another food that strongly evokes the South is barbecue. While much of the rest of the United States uses the term to refer to a backyard cookout, southerners use it quite particularly to mean the slow smoking of meat over hardwood coals. The meat is almost always pork.

Green glaze collards were introduced in South Carolina by Philadelphia seedsman David Landreth in 1820. Landreth developed this unique variety of worm-resistant cabbage so that southern gardeners would enjoy larger yields. Boiled collard greens and the pot broth are one of the cornerstones of southern cooking. PHOTOGRAPH BY L. WILBUR ZIMMERMAN. ROUGHWOOD SEED COLLECTION.

Southerners have long had a thing about swine. William Byrd, a Virginia planter, observed in the early 1700s that his neighbors were eating so much pig flesh that they “seem to grunt rather than speak.” Before refrigeration became common, pigs were usually slaughtered when the weather turned cold in late autumn—“hog-killing time”—and the meat was preserved as bacon, sausage, salt pork, or hams rubbed in spices and allowed to cure for months in a smokehouse. Little of the hog was wasted. The small intestines were breaded and fried or boiled as chitlins, and the fat was rendered into cracklins that flavored cracklin cornbread.

Of all the uses of pork, barbecue is probably the most popular. In the beginning the dish was usually served at political rallies and other community get-togethers. By the end of the twentieth century it was more commonly served at casual restaurants, universally known as barbecue joints, where everyone from blue-collar laborers to white-collar professionals sit cheek by jowl mopping barbecue sauce from their lips.

Southerners love to argue the merits of different barbecue styles. Two areas are particularly known for their expertise. In the Carolinas pit masters smoke whole hogs at gatherings called “pig pickin’s” and serve the meat pulled from the bone with a spiced vinegar sauce that, unlike most barbecue dressings, contains no tomatoes or ketchup. In parts of South Carolina the sauce is mustard-based. Meanwhile in Memphis, Tennessee, the self-

described “pork barbecue capital of the world,” pork ribs or chopped pork shoulders are served in sandwiches with creamy coleslaw. People in Memphis love barbecue so much that some restaurants serve barbecue-topped pizza and barbecue spaghetti, pasta tossed with barbecue sauce.

### Changing Tastes

The last half of the twentieth century brought rapid change to the South. The civil rights movement engineered a revolution in race relations, business and government invested heavily in the region, and air conditioning made it more comfortable to live there. Millions of outsiders moved south for jobs or retirement, bringing their tastes and customs with them. In fast-growing areas like Atlanta, Georgia, or Charlotte, North Carolina, it is almost as easy to find a bagel as a biscuit.

In the midst of this evolution southern cooking enjoyed something of a revival, as natives and newcomers alike came to regard it as another ethnic cuisine to be discovered or rediscovered. Native sons and daughters like Craig Claiborne, Edna Lewis, and Nathalie Dupree celebrated the region’s foods in cookbooks and television cooking shows. A new generation of chefs lavished their talents on the old cuisine at high-end restaurants from Arkansas to Virginia. Popular road-food guides told travelers where to find the best barbecue joints, seafood shacks, produce stands, ladies’ tea rooms, and meat-and-three-plate lunch emporiums.

Even so, traditional southern home cooking seemed to be fading. Fewer people had time to make messy, demanding dishes like fried chicken. Some avoided them altogether out of concern for fat and cholesterol. Old-fashioned southern food was increasingly left to restaurant kitchens or rolled out only on special occasions.

Yet southerners remain deeply attached to their foods and rituals. In a nation that relentlessly wears down regional distinctions, their shared foodways are one of the few things that knits them together and reminds them who they are. How else to explain the enduring appeal of grits, the unremarkable cornmeal porridge that is one of the region's most joked about icons?

Shelby Foote, the Mississippi-born novelist and historian, takes his culinary heritage seriously. Once, when he was staying in a hotel, he hung a breakfast order on his doorknob asking for grits. Room service brought him hash browns instead. Yankees eat hash browns with breakfast. He put out the card again, this time with a note: "This morning you brought me potatoes. Do not commit this outrage again."

## THE SOUTHWEST

The Southwest encompasses New Mexico, southwestern Texas, Arizona and the southern part of Colorado that was settled by the Spanish. Although all of Texas is sometimes considered part of the Southwest, much of east Texas is more closely related to the Southeast and much of north Texas is more related to the Midwest and the West.

Southwestern foods in the United States are a product of the foods of the Native Americans and the foods of Spanish and Spanish-Indian settlers from Mexico. This tradition appears in the areas that have been settled the longest. Its distribution follows a roughly north-south line starting in southern Colorado, especially along the San Luis Valley, and proceeding southeast along the Rio Grande River, including the cities of Santa Fe, Albuquerque, and Las Cruces, New Mexico. In Arizona, the line is roughly an east-west one, marked by the Gila River, below which are long-established Spanish-Mexican settlements. In Texas the Southwest can be described as being south and west of San Antonio. Traditional food is also found in other communities in the region, as individual families have moved to establish new homes.

Outside of the traditional areas, communities of the Southwest reflect a food tradition that is more Eastern or Midwestern than Southwestern. In some cases it may also represent the simple ranch cooking of the Mountain States of Colorado and Utah. Inhabitants of larger cities in the Southwest represent many different cultures, as is the case with cities elsewhere in the United States. Asians, Africans, Europeans, Latin Americans, and people from many countries in the Middle East and the Indian subcontinent all have their own enclaves, giving rise to a broad variety of markets and restaurants. Tucson, Arizona, far from the largest of the cities in the Southwest, boasts a cultural and food festival each October that regularly has more than fifty different ethnic food booths. While some families cling to their ethnic food traditions, especially in isolated communities, others are more likely to celebrate their inherited food culture on special holidays. It is not unusual in the Southwest to find a family enjoying its own native cooking one evening, while exploring flavors from another on the next.

## Traditional Foods in the Southwest

Traditional Southwestern food is commonly viewed by persons living outside the Southwest as consisting of tamales, tacos, enchiladas, tostadas, and burritos. While these dishes are extremely popular in many restaurants, they are referred to in the culinary repertoire as *antojitos* (snacks).

Traditional to the old Southwest are slow-cooked stews and slow-grilled foods, served with beans, rice, and corn tortillas. Vegetables used include squashes, *nopales* (pared and trimmed pads from the prickly pear cactus), jicamas (spherical tubers that, when pared, have a crisp texture and a faint taste of apple or water chestnut), purslane, and tomatillos (tart fruit that resemble tomatoes with husks but are related to the cape gooseberry). Avocados are used to make guacamole (a thick sauce of crushed avocado with seasonings). Fresh cilantro (also known as coriander), is used frequently to season fresh, quick-cooked dishes. Many of these foods existed in the diet of the Native American before the arrival of the Spanish. Opinions differ on whether chilies were grown

in the Southwest before the arrival of the Spanish from Mexico, but the variety of spices that create the chili-based dishes today, both within the Native American culture and outside, arrived with the Spanish.

Food specialties of the Southwest differ from region to region. The burrito (a soft flour tortilla wrapped around a hot, savory filling) originated in the area north of the state of Sonora, where the flour tortilla originated. Stacked enchiladas (corn tortillas prepared as for rolled enchiladas but layered flat with savory fillings) are a specialty of New Mexico, although their popularity has spread throughout the region. *Salpicon* (a shredded-beef salad with vegetables) is a hallmark of southwest Texas.

### Elements of Traditional Southwestern Cooking

Tortillas, beans, rice, vegetables, and some meat and cheese are the mainstays of traditional Southwestern cooking. In areas within driving distance of the Gulf of California, fish and shellfish increase the choices. Apart from the well-known *antijitos* mentioned earlier lie the true gems of Southwestern cuisine: red chili con carne (chili with meat) made with meat simmered in a sauce of reconstituted dried red chilies, cumin, dried coriander and oregano; and green chili con carne made from meat simmered in fresh green chilies, onions, garlic, and tomatoes. Beef, pork, lamb, and goat are all used, although beef is the most common in restaurants. Chicken is also cooked with sauces made from either red chilies or green chilies. These dishes vary from town to town and family to family. Beans are usually served separately, not as a part of the chili stews. While chili stews are slow-cooked, fish and shellfish may be quickly grilled. Chicken is marinated in a mixture of orange juice and spices before being grilled, and steak is often marinated, then grilled for *carne asada* (literally translated as “roasted meat”). The cheese used in many popular Southwestern restaurants is either Longhorn cheddar or Monterey Jack, with sour cream used as a garnish. In the barrios (the Hispanic-Mexican neighborhoods) and in the homes of serious Southwestern cooks, Mexican *queso fresco* (literally “fresh cheese”) and commercially made Mexican *crema* (similar to sour cream) are used instead.

**Chili.** The dish known as “chili,” much beloved in the region, is a creation of U.S. cooks. True aficionados eschew tomatoes or beans in their chili, preferring to have their meat, either cubed or coarsely ground, simmered only in a sauce made from reconstituted dried red chilies, spices, and other flavorings. Contests are held throughout the region to determine the best chili. Private cooks and restaurants often take liberties with this tradition, producing their own variations.

**Tortillas.** Tortillas in the Southwest were traditionally made with either yellow or white corn, and sometimes with the more exotic red or blue corn. These corn tortillas are made from corn that has been soaked in slaked lime and then ground. They require no fat of any kind

and are cooked on an ungreased *comal* (griddle). The tortilla acts as a wrapper or as bread. Occasionally, wedges of tortilla are crisped as a snack. Nachos (crisp wedges of corn tortilla topped with cheese and other garnishes) are a recent invention. While crisp, folded corn tortillas are served with fillings as tacos, the more authentic style for a taco is simply a soft, warm tortilla.

The flour tortilla native to the Mexican state of Sonora, sometimes as much as eighteen inches in diameter, is a more recent addition to traditional foods. The traditional flour tortilla of northern Sonora is a thin disc made from flour, water, and lard patted into shape by hand, then cooked quickly on a large hot griddle. These large tortillas are used to wrap foods, but they also are spread with butter and crisped before cheese and occasionally other toppings are added to form a crisp snack that resembles pizza. Flour tortillas are also made into quesadillas (tortillas folded over cheese and other fillings and grilled or fried). Small flour tortillas used in place of corn tortillas are an addition of the twentieth century, as is the inclusion of baking powder in the dough to give the flour tortilla a puffy quality.

**Tamales.** A *tamal* (plural, *tamales*) is a packet of corn-based dough that is stuffed, wrapped in softened corn husks, and steamed. The corn husks are removed at the table before the tamales are eaten. While tamales are served throughout the year in restaurants in the Southwest, beef and red chili tamales are traditional for Christmas when families and friends gather to assemble dozens of tamales. A traditional Christmas *tamal* is made from *masa* (a dough of corn treated with slaked lime, which is whipped with lard or shortening to make it fluffy), with a filling of shredded beef that has been stewed with red chilies and spices. Fillings used throughout the year may be made from slow-cooked chicken, beef, pork, lamb, or goat, which have been seasoned with reconstituted dried chilies and with spices.

The green corn *tamal* is a specialty of midsummer and best known in southern Arizona, although green corn tamales are also made in New Mexico. Although the green corn *tamal* is now available frozen year round, it is best fresh when corn is in season. The best green corn *tamales* are made from field corn, the kind given to animals for fodder. The fresh corn dough is filled with cooked green chilies and cheese, and the *tamales* are traditionally prepared as above.

**Chilies.** Many chilies, both red (which is the ripe form) and green, are grown in the Southwest, but the variety of chilies available, however, is not as diverse as it is in Mexico. Each variety of chili has its own special use, alone or in combination. Green chilies appear in fresh salsas (sauces) but also appear in stewed dishes, depending on the flavor desired. Red chilies are dried for use throughout the year and are reconstituted for use in cooked salsas and slow-cooked dishes. The combination of different red chilies with spices and herbs such as ground coriander

der seed, ground cumin seed, and oregano or fresh coriander leaves (cilantro) gives each dish its special character. Chilies, even those from the same plant, can vary in piquancy. Traditionally, the piquancy has been rated in Scoville units, where higher readings indicate a higher degree of piquancy. Some experts now question the value of that practice as different humans react somewhat differently to levels of piquancy.

**Beans.** Simmered dried beans, the mainstay of traditional Southwestern cooking, are usually *charro* beans (cowboy beans), but beans may be simmered or baked with various flavorings. “Refried” beans are not fried twice but are cooked beans mashed into shortening and seasoned with onion, garlic, and other seasonings.

**Barbacoa and grilled foods.** While not as widespread as the ubiquitous red or green chili-flavored stews, pit-cooked meats and grilled meats, chicken, and fish are also elements of Southwestern cooking. Slow pit barbecuing traditionally was done using the head of the animal, although today other cuts are used. Grilled meats include *carne asada* and chicken marinated in orange juice and spices and then grilled.

**Fried breads and sweets.** *Sopaipillas* (made from quick dough of wheat flour and baking powder, rolled out, cut, and deep-fried so that they puff up) are served as a savory bread with meals in parts of New Mexico. In Arizona, these are occasionally served with savory seasonings, but are more likely to be served as a dessert with honey. Southwestern desserts are fairly simple, serving as a soothing and cooling finish to a meal. A favorite is flan (a molded baked custard). Another is *almendrado* (an almond-seasoned mixture of egg white and gelatin served with a custard sauce). *Bizcochitos* (anise cookies) and *buñuelos* (deep-fried wheat-flour pastries) are popular as well.

**Drinks.** While the Margarita (a mixture of Tequila, lime juice, and orange liqueur) is popular in Southwestern restaurants, Mexican beers are more often drunk with foods in the Southwest if an alcoholic beverage is desired. Many nonalcoholic drinks are available in Hispanic-Mexican neighborhoods shops and restaurants, including *tamarinda* (a sweetened drink made from tamarind pulp), *borchata* (sweetened rice drink), and *aguas frescas* (literally “fresh waters”) made from various fresh fruits.

### The Food and Culture of the Southwestern Native American

The importance of corn in the food life of Native Americans cannot be overemphasized. Corn is essential and sacred; corn is life itself. In many pueblos the day begins with a sacrifice of corn. Corn originated in Mexico in about 2500 B.C.E., but required hybridization before it was useful as a food. Contemporary Pueblo Indians plant corn with great ceremony and care. Corn appears in the Native-American diet today in the form of tortillas. It

The meeting of Mexican and Navajo Indian come together in this southwest invention, the fry-bread taco. PHOTOGRAPHED AT CANYON DE CHELLY NATIONAL MONUMENT, ARIZONA.

also appears as hominy and *posole* (corn kernels that have been treated with slaked lime so that they swell and release nutrients bound inside). *Posole*, sold dried and made of yellow, white, red, or blue corn, refers to a soupy stew that is made with simple ingredients, including seasoning of chilies for everyday fare and with meat for festival occasions. Another significant part of the diet of the Southwestern Native American, beans are planted with the same kinds of sacred observances as corn. While the most common bean in the Southwest today is the pinto bean, a wide variety of beans, some extremely flavorful, were a part of the Native American diet in the past. As seed savers work to isolate some of these “heirloom” beans and grow them, some of the old varieties are again becoming available not only to the Native American but also to the general public.

While the hunting, gathering, or growing of food take on a sacred aspect, the act of preparing food is an important and time-consuming activity. Among the Pueblo Indians and other nations, the act of stringing red chilies to dry each autumn takes on a special significance, for there must be a string of chilies equal to the height of each person in a family to sustain the demand for the coming year.

The popularity of foods such as Indian fry bread, (dough cooked on a hot stone) came with the increased availability of refined flour and commercially prepared shortening or lard. From a culinary standpoint, fry bread and *sopaipillas*, mentioned earlier, are essentially the same. The “Navajo taco” employs fry bread rather than a tortilla as its wrapper. While this increased use of fat and flour has provided flavorful alternatives to the corn tortilla, the consumption of significant quantities of these ingredients has altered the diet of the Southwestern Native American to the extent that obesity and diabetes are rampant. Efforts of such organizations as Native Seeds Search to preserve the original foods of these peoples are

intended to at least partially encourage a return to a more healthy diet.

**UTENSILS, COOKING.** Among professional cooks, cooking implements in the kitchen are referred to collectively by the French term *batterie de cuisine*. This includes all utensils involved in the preparation of food regardless of specific function or type of material (ceramic, metal, glass, wood). The range of utensils in any given kitchen speaks volumes about the elaborateness of the cooking that takes place there as well as the type of food prepared. There are also large cultural differences in the implements deemed necessary for food preparation, so the *batterie de cuisine* of a Chinese kitchen is quite different from that of a kitchen of medieval Syria, ancient Rome, or a modern American hotel. From the standpoint of culinary history, the study of cooking utensils falls under two broad categories: archaeology for the ancient and medieval utensils, and material culture for objects of more recent date. Because of their beautiful design, cooking implements are also of interest to certain branches of decorative arts and antique collecting.

Archaeologists rely almost exclusively on utensils in their attempt to reconstruct cuisines of the past, especially when there are no written records to provide working recipes. It is known that the Roman cookery book of Apicius was originally illustrated with pictures of utensils because there are a few scattered references to these pictures in the surviving text. Medieval scribes did not bother to copy those pictures. If they had, modern food historians would have a better idea of what some of the mysterious implements mentioned in Apicius looked like. But the fact that the original cookbook contained pictures of unusual utensils is evidence in itself that certain recipes in Apicius were not familiar even to most educated Romans.

The Austrian food ethnographer Anni Gamerith revolutionized the study of cooking utensils during the 1970s when she published her studies about the relationship among food types, utensils, and heat source (open hearth or enclosed cook stove). Heat source determined the design of the utensils, and this functional reality determined the range of dishes that could be accomplished with that technology. To be certain, the *batterie de cuisine* of a typical farm kitchen or even of a well-equipped kitchen in an urban townhouse not only reflected the type of dishes made there but also inventoried the economic level of the household, where it fit into the larger social picture. The kitchen and its implements thus become critical keys in understanding the foods of the past.

Cooking utensils can be organized into several categories depending on their function and the kind of cooking that is done. The categories include preparation equipment; pots, pans, frying pans, and cauldrons; griddles and equipment for roasting and baking; utensils for tabletop cooking; and utensils used for charcuterie.

#### Preparation Equipment

Preparation equipment includes spoons, spatulas, meat forks, knives, cutting boards, scissors, and shears. Grinding, crushing, straining, sifting, and sieving implements are also part of this group, as are whisks and beating devices that range from the most primitive handful of twigs bound together with string to the most powerful food processors and blenders. Ceramic, glass, and stainless steel bowls fit into this category as well. Measuring devices vary from country to country, depending on the weight system used. Most countries use a metric system for measurement of both liquids and solids, although the actual number of units to the measure may vary. Home cooks in the United States use a system developed in the late nineteenth century that employs measuring spoons and measuring cups (different kinds for dry or liquid measuring), but the body of measurements used in American cookery (pounds, ounces, quarts, and so forth) dates to Elizabethan England and represents a system of measure that is both archaic and at odds with that of the rest of the world.

#### Pots, Pans, Frying Pans, and Cauldrons

Pots, pans, kettles, skillets, cauldrons, and frying pans are included among items that are placed on an open flame or directly over a heat source. These utensils have the longest history of use, as they were first used over open fires. There were also critical differences in their designs. A kettle, for example, was characterized by straight or outwardly splayed sides. It was generally used uncovered for boiling foods or reducing them to another consistency, as in the case of large copper apple butter kettles. On the other hand, a traditional pot bulged on the sides and featured a neck below the rim. It was often used for cooking several things at once and invariably included a wooden or tin lid. Pot lids were normally sold separately

from the pot itself but were usually numbered to match the number on the pot, such as “5” for five gallons, or “10” for ten gallons. Cookpots (one word in colloquial American usage) were generally small and made of ceramic. They were employed in cooking foods that would be spoiled in color or flavor if they came in contact with an iron pot or kettle. Classic New England baked beans were originally baked in ceramic cookpots set on a trivet among the hot coals.

Frying pans were known in ancient Greek and Roman kitchens: *téganon* to the Greeks, *patella* to the Romans. The Roman *patella* survived in modern Spanish as *paella* and in modern Italian as *padella*. Frying pans were probably also used to prepare grain dishes, the antecedents of paella made with rice. Skilletts were originally deep, much like modern sauce pans, but the term is used interchangeably with frying pan. It is common practice among American cookbook writers to forego the use of “frying pan” altogether in favor of “skillet,” as in the phrase, “brown lightly in a skillet” rather than “brown lightly in hot fat in a frying pan.” This word manipulation is an attempt to make the recipe sound more appealing and less fatty although the ingredients remain the same. Frying pans with legs, once common in open hearth cookery, were generally called spiders both in England and in America.

“Pan” is a term of truly ancient origin, deriving from Celtic *panna*. The feature that distinguished it from other utensils was its flat bottom. This is why sauce pans and sauté pans, while very different in shape, are nonetheless called “pans.” A versatile pan that combines the best of both the sauté pan and the frying pan has higher, sloping sides that are often slightly curved. This pan is called a *sauteuse* (literally a sauté pan in the female gender), an *evasée* (denoting a pan with sloping sides), or a *fait-tout* (literally “does everything”). Most professional kitchens have several of these utensils in varying sizes.

The cauldron evokes a vision of a huge pot boiling fiercely over an open fire. Actually the traditional cauldron was used in much more diverse ways, sometimes containing several different foods in smaller, sealed containers or wrapped in cloth. It is far more likely that the cauldron gently simmered than rapidly boiled. The word itself is of Celtic origin, and this one hearth utensil was universal throughout Celtic-speaking Europe. It was the symbol of hospitality, was used in religious rituals, and was often mentioned in Irish myths. Judging from archaeological evidence, the most ancient cauldrons were shaped like bowls. The Belgic Celts used cauldrons in the preparation of fish stews, which they made on board their fishing boats. These stews, called “chowders,” were adopted by the Roman navy, survived through the Middle Ages, and have many counterparts. One unifying feature of all chowders prepared in a cauldron was the lining of cabbage leaves (later coarse dough) that separated the food from the metal, thus preventing it from taking on the taste of the pot.

Detail of a page from the 1857–1858 catalogue of cast-iron utensils manufactured by Savery & Company of Philadelphia. Note the careful terminology given to each of the different shapes: oval oven (top left), deep spider and shallow spider (bottom right), and pot (top right). Pot is synonymous with cauldron and by strict definition must have a bulging body and neck or rim as shown in the catalog. Pots were sold with or without lids. ROUGHWOOD COLLECTION.

## Griddles and Equipment for Roasting and Baking

Griddles, grill pans, and irons for baking and toasting fall into another category of cooking utensil that also includes open outdoor and indoor grills and rotisseries. In one of the most effective rotisseries, the flame is arranged vertically, and the food is arranged on rods before the fire. These are most often used in commercial environments, including permanent food stalls in some countries. Griddles are used for pan grilling and for hearthside baking in much of the world, from the crumpets of England to the tortillas of Mexico, and the Hopi Indians used a special stone griddle to make *piki* bread. Irons are used for forming special cookies, but they also include hinged

An assemblage of utensils showing how an Appalachian dish of squirrel, potatoes, and maize would be baked on the hearth in the 1830s. A brown stoneware baking dish has been placed on a hanging griddle. The tin bonnet reflects heat from the hearth back towards the food so that it cooks evenly. ROUGHWOOD COLLECTION.

irons for making waffles, hinged and ridged irons for producing *panini* (a grilled sandwich that originated in Milan), and the characteristic shell design of the iron to form the French *croque monsieur* (a grilled ham and cheese sandwich).

Roasting pans and equipment include spits, dripping pans, and roasting pans for use in ovens. Skewers also fall into this category, as when they are used in a tandoor oven, although they may also be used for grilling.

Baking and pastry work calls for yet another set of equipment. Such items include plaques (baking sheets) and pans and dishes especially designed for this use. This category includes frozen and chilled desserts as well, bringing into play molds of various kinds. Bread baking often employs flat baking stones that permit the retention of heat and, in combination with steam, produce a crisp crust. Loaf pans are also employed in bread baking and dessert making.

### Utensils for Tabletop Cooking

One classification that crosses over into table service is equipment for tabletop cooking. This includes fuel sources, such as spirit lamps, alcohol burners, Sterno (a commercial fuel), or butane. Tabletop or tableside cookware includes the chafing dish, in which a sauté pan is set over simmering water over a heat source, the oval skillet for finishing dishes over a flame at table side, and the Mongolian firepot. The latter is a device, frequently made from brass, in which a central chimney is set above a heat source. Liquid, usually broth of some kind, is heated and added to the pan that surrounds the chimney. Guests then cook their own food, such as a variety of meats, poultry, and vegetables, in the simmering liquid. Fondue pots, pottery for cheese fondue and metal for meat or fish fondues, are also used to cook at the table.

### Utensils Used for Charcuterie

A final category of cooking utensils is those used for making charcuterie (*pâtés*, terrines, galantines, and sausages). These include grinding and stuffing equipment for sausages and specialized baking dishes for various kinds of charcuterie loaves. A terrine, as a utensil for baking the dish of the same name, may be pottery or enameled cast iron. Forms for *pâté en croûte* (loaves baked in pastry of some kind) often have designs in the sides to make the pastry case more attractive when baked.

### Materials Used in Cooking Utensils

While fired clay, bronze, and iron pots were used for many centuries, copper pots were also found in the Middle East, Europe, and North Africa. In addition, porcelain, aluminum, stainless steel, and glass have become common, and newer materials develop as stove technologies change.

As hearths evolved, so did the designs for various kinds of utensils. As a wider variety of materials became available, some were judged better for specific kinds of cooking. Thus, although cooking utensils are sold in sets of different shapes and sizes but all made of the same material, some usually are better fitted to a specific cooking function than others. The function also depends on how well the metal conducts heat. Sometimes a great deal of heat is required, as in sautéing or searing meats. In some cases, slower heating but fine heat retention is needed. Utensils made of certain metals are preferred by expert cooks for the superior results they produce. For example, where it is important to conduct heat quickly and remove it just as quickly, as in sautéing to just the right degree of doneness, copper lined with tin, stainless steel, or nickel is excellent, and aluminum is a close second. That is not to say that utensils of other metals cannot be used for those purposes; they simply are not as effective.

For long, slow cooking, heavy cast iron holds heat evenly and permits simmering at relatively low temperatures, as does clay (although, except in the case of the Japanese *donabe* cooking pot, clay utensils cannot be used

over a direct flame). Steel, on the other hand, has low conducting properties and is useful for foods to be cooked in a large amount of boiling water, for example blanching vegetables. Ceramic and glass materials may be used for baking and are also used in tempered-glass double boilers.

Some metals, notably copper, aluminum, and iron, interact with foods cooked in them and must be lined with another metal to be used safely with food. Copper can be used unlined for boiling water, melting sugar, and beating egg whites. Since acid and eggs interact with copper, pans used to cook them are generally lined with tin, nickel, or stainless steel.

Iron and aluminum, like copper, interact with some foods. Unlined cast iron or aluminum interacts with eggs and acidic foods like tomatoes. Cast iron is often enameled to reduce this problem. Aluminum can be lined with stainless steel, which is nonreactive. Some aluminum is treated to make its surface nonreactive.

One of the finest materials for slow simmering in ovens remains low-fired clay. It holds heat well and even imparts a flavor or quality that metals cannot provide to a dish. For higher-heat work, such as soufflés, highly fired porcelain is preferred by some cooks, although others use glass or tinned steel.

The thickness of the material used in a utensil also affects the quality of the results. Thin metal utensils tend to warp easily over heat. Thin pottery, porcelain, or glass breaks easily and does not hold heat. Thickness, however, also implies weight. Professional-weight copper utensils are heavy, especially in larger sizes, as are cast iron ones. This is one of the reasons lined or anodized aluminum is preferred by some cooks.

### Form and Function in Cooking Utensils

Function determines the shape of a pot or pan nearly as much as the material from which it is manufactured. In sautéing, for example, a wide pan with three-inch straight sides and a long handle permits the food to be shaken and tossed easily without falling from the pan. Moisture evaporates quickly, preventing food from being steamed rather than sautéed. Pots used for long braisings, on the other hand, have higher sides to concentrate the contents and prevent evaporation. Such vessels have closely fitting lids as well. Stockpots are traditionally tall in proportion to the diameter to minimize evaporation during the long, slow simmering process. Some stockpots in professional use for restaurant work, however, are wider than they are tall to allow evaporation of a large amount of liquid and concentration of flavor.

Professional kitchens also have the challenge of handling large amounts of food that make enlarged utensils heavy and awkward. Giant stockpots either turn on gimbals for easy pouring or have spigots at the bottom to draw off liquid. Braising devices for banquet work are often large, rectangular devices, four feet long and two feet

wide or more, and are arranged on gimbals so the pan can be tilted easily. Overall, the utensils and cooking equipment of the large, professional kitchen have a far more industrial appearance than cooking utensils used in a home.

### Differentiation of Use in Forms of Cooking and Cooking Utensils

The anthropologist Claude Lévi-Strauss notes, in both *The Raw and the Cooked* (1969) and *The Origin of Table Manners* (1968), that in certain tribes, some cooking functions were reserved for men and others for women. In his example, the roasting function (representing something that was somewhere between raw and cooked) was reserved in certain tribes to men, while boiling (which represented something that was well cooked and was even associated with the start of decay) was reserved to women. Lévi-Strauss also mentions that roasts are more often served to guests or at feasts, while boiled or simmered foods are considered everyday food. In the Middle East, cooking methods associated with hunting, roasting, or grilling over a campfire were reserved for men. The tradition has become common among Americans, where many men handle outside grilling at home.

Cooking utensils sometimes are reserved for special functions related to religion. The Jewish laws of kashruth dictate that separate utensils be used for dairy meals and for meat meals. They further direct that either a completely different set of utensils be used for the feast of Passover or the utensils be ritually prepared for Passover by a special boiling process. This grouping of utensils by food type was also practiced by many peasant societies in Europe, especially in areas where ceramic utensils predominated. Since pottery absorbs food flavors (onions and fats in particular), many households maintained separate utensils for fish, meat, and milk preparations.

**VEAL.** *See* Cattle; Mammals; Meat.

**VEGETABLES.** Vegetables are plants considered fit for human consumption, although they may also double as fodder crops for domesticated animals. As cultural metaphors, they are firmly embedded in all languages and emerge in such expressions as “hot tomato” for an attractive woman, “cabbage head” for someone who is not too bright, or “cool as a cucumber” in reference to extremely calm nerves. However, from a scientific standpoint, the use of the term “vegetable” is highly subjective and is a term of convenience rather than one based on a neatly ordered scientific classification. This ambiguity evolved out of horticultural practice and to some extent out of cultural bias hinging on the key question: what is fit to eat? The vegetable of one culture may be repulsive to another, as, for example, the cannibal’s tomato (*Solanum uporo* Dunal) of Melanesia and Polynesia, which was formerly used in salsas for human flesh. On Fiji, the berry was actually cultivated near sites designated for human sacrifice.

Vegetable classification as defined by Western culture derives in part from prescientific attitudes about the mythic world to which those plants belonged in antiquity. Both the Greeks and Romans—and most other ancient Mediterranean peoples—differentiated between two types of edible plants, *holera* or *olera* (cultivated plants) and *borta* (wild plants gathered as food). This dichotomy was presided over by different sets of deities who represented fundamental attitudes about human society and its relationship to nature. We have inherited this structural framework insofar as vegetables are now exclusively defined as oleraceous or esculent herbs, as cultivated in the *bortus oleritus* (kitchen garden). Thus the formal botanical term for growing vegetables is “olericulture.”

The idea that certain vegetables were suitable for boiling (or conversely that only boiling plants were “vegetables”) was highly developed even in ancient Greece. The implication arising from this was that these plants were also worthy of domestication. The ancient Greek physician Diocles of Carystus even went so far as to note that, among the *borta*, beet greens, mallows, sorrel, net-

tle, orach, iris corms, truffles, and mushrooms were the most suitable for boiling. His beet greens were the ones found growing near the sea, not those cultivated in gardens, presumably the wild ancestor (*Beta vulgaris* L. spp. *maritima*) of the present-day cultivated sorts.

In most romance languages this association with boiling or poaching is further reinforced by such cognates of *oleritus* as Spanish olla (a cook pot or stewing pot), implying that the kitchen garden is designed to produce plants mostly earmarked for treatment in hot water. This connotation is clear in the word *Gemüse*, the German term for vegetables that derives from the medieval German *Gemiisz*, a mush or porridge. The idea of cooking or boiling the plants is preeminently expressed in the French term *jardin potager*, literally ‘a garden for pot dishes: soups and stews.’

The French have also provided English with the word “vegetable.” Its most literal meaning is plain: edible vegetation. The accepted origin of the word is that it derives from Medieval Latin *vegetare* via Old French *vegeter* (to vegetate). The classical Latin root is generally given as *vegetus* (lively or active), although this line of linguistic evolution may be subject to revision as more research on French links to Gaulish comes to light. In any case, the old meaning of “vegetate” did not imply something in decline, a common modern connotation, but rather something that was springing to life, a profusion, a natural bounty expanding from seed almost to the extent that it could be heard rustling as it grew—the complete opposite of the gardens of Adonis discussed later in this essay. This concept of vegetal fecundity is quite in line with Celtic ideas about food and nature and is especially characteristic in the obvious lack of definition between the cultivated and uncultivated worlds. Thus, in its root meaning, the English word is more all-inclusive than the Mediterranean concepts of *holera* and *borta*.

This ambiguity is best exemplified by the vast range of plants that are called vegetables in the English language. Tomatoes are berries, yet they are called vegetables. Garlic is considered a vegetable, yet one does not eat the leaves. And what about rhubarb stems, which are treated like a fruit (the leafy part is poisonous), or the sunflower, which is consumed as a seed or as oil? Where does edible vegetation fit in? Most garden books define

Ceramic vegetable steamer with deep red glaze by Virginia potter David Norton. The concept is based on the Yunnan pot of China, which features a cone in the center and holes for admitting steam. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

vegetables as annuals because they are grown to crop for one season only, yet many of these plants are true biennials (celery, carrots, cabbage, leeks, turnips), and some are even perennial (rhubarb, horseradish, sweet potatoes, asparagus, sorrel, peppers).

Another method for defining vegetables was based on the part of the plant considered most esculent for consumption. Here we have the rather simplistic division of the plant world into root vegetables (such as parsnips), pod vegetables (cowpeas, for example), and leaf vegetables (spinach and chard to name two). Again, while it is easy to imagine carrots as root vegetables, lima beans as pod vegetables, and collards as leaf vegetables, the unending discovery of edible plants from exotic locales such as Africa and South America has challenged all Old World definitions of this classification.

In this category is the East African oyster nut (*Telfairia pedata*), a rampantly vining cucurbit that is normally planted at the base of trees large enough to support the heavy fruit. In fact, several vines—both male and female—are grown on the same tree and will produce large squash-like fruit for up to twenty years. But it is the seed, not the fruit itself, that is eaten. Once established, the vines are not given much attention. While oyster nuts are intentionally planted around trees conveniently located near dwellings, this is a vegetable crop based more on passive intervention than on formal horticultural practice. This is a pattern once common in hunter-gatherer societies, where certain patches or stands of useful wild plants were periodically tended and encouraged through selective weeding to produce higher yields.

The yacon (*Smallanthus sonchifolius*) of South America is similarly outside the norm, for it produces crunchy, sweet-tasting tubers that are eaten like fruit. It has been cultivated in the High Andes for so many centuries and reproduced by root division for such a long time that many varieties can no longer produce fertile seeds. They are utterly dependent on humans for survival. Since it is low in calories, the tuber has been recently reevaluated as a possible diet food.

This continuing botanical revelation has also altered dietary schematics. Old peasant foraged foods like dock have been rediscovered as biodynamic or macrobiotic, synonyms for well-being, longevity, and psychological balance. In this way the vegetable has repeatedly inserted itself into the most radical of lifestyle movements—but this is hardly new, since vegetarianism and the dietary significance of plants has played a key role in philosophical approaches to nutrition since the days of Pythagoras or even since Adam and Eve, the original vegetarians.

### Vegetables in the Fertile Crescent

Eden was said to be somewhere in ancient Mesopotamia. About the original garden we know little, but the Mesopotamian peoples left vast heaps of cuneiform tablets that reveal detailed information about the vegetable plants they once cultivated. As the climate grew hotter and drier many thousands of years ago, a vivid visual distinction evolved between cultivated and uncultivated ground. In fact, the vegetable gardens of that era were enclosed by walls both as protection from wandering livestock and as a means to contain and define the area where precious water would be distributed. Furthermore, it is clear from most of the records, whether Assyrian, Babylonian, or of any of the other cultures sharing the Fertile Crescent, that vegetables were commonly grown around date palms or fruit trees. The palms filtered the blasting sunlight and gave the garden the appearance of a welcoming grove. Thus the garden was also a place where socialization took place and indeed became a place sanctified by its own gods and protective forces.

Archaeological remains (mostly seeds) from this region also support what is documented in clay tablets. The range of vegetables included many still familiar: cucumbers, chards, gourds, onions, garlies, leeks, melons, chickpeas, lentils, cress, kales, and sesame—both for the seeds and for the oil. Colocynth melons, which resemble small watermelons, were grown primarily for medical applications. Some modern Arabic words, such as *kurrat* for a type of leek, can be traced to ancient texts from this period, proof of the long continuity of many of these vegetables. Indeed, even the Arab word for vegetables, *baql*, traces to ancient Aramaic *buqul*.

Tablet inscriptions also point to another feature of vegetable culture that suggests highly developed horticultural practices: specialization. There are numerous references to the “cucumber place” or to the “garlic place,” which implies that entire beds were devoted to

one type of vegetable and that in many cases this was the sole crop raised by the grower. Garlic was especially valued in this respect and even was used as collateral in financial agreements. In texts where a year-to-year continuity can be reconstructed, it is evident that a garlic place may change into a chard place, so some system of crop rotation must have been in effect. This concept of agricultural specialization was thought to have been perfected by the Phoenicians and codified by Mago, whose great work on agriculture (lost in the original Punic) was highly respected by the Romans.

The Phoenicians were also great middlemen in trading vegetables and seeds throughout the Mediterranean. They are thought to have spread the culture of shallots and artichokes well beyond the eastern Mediterranean, and are known to have introduced the intensive cultivation of saffron into North Africa and southern Spain—saffron was primarily a dyestuff and secondarily a ritual herb. Many Punic words for specific vegetable varieties reflected this plant exchange, as, for example, in *koussimezar* (the Mezar melon or Egyptian “cucumber”), an egg-shaped melon, one of the earliest types to come out of Africa.

### Vegetables in Egypt

There is a large body of published material on the history of gardening in ancient and pre-Islamic Egypt, but there are no books per se devoted exclusively to vegetables. Orchards, trees, flora, landscape gardening, and even aquatic plants have received thorough coverage, yet the vegetable stands alone in this curious neglect. Vegetables in general have been viewed as poverty food by most cultures, especially when they form a large portion of peasant diet. Egypt was no different in this regard.

The fine gardens of ancient Egypt were enclosed like those of Mesopotamia and contained trees, flowers, even ponds for fish and ducks. The gardens of the peasants were mostly simple agricultural plots devoted to a specific mix of vegetable crops associated with the local economy, as, for example, lentil or onion growing for absentee landlords in large urban centers like Alexandria. On the other hand, vegetable gardens within temple precincts were often quite elaborate and were intended to supply the priesthood with a full range of food as well as offerings for the deity. Lettuce, for example, was important to the cult of Amun-Min, thus its cultivation held both culinary and religious significance. Indeed, temple gardens were considered to be part of heaven, like the temple itself, so vegetables from those gardens achieved a purity unlike those from the common world.

Papyri and tomb paintings have provided a rich array of material dealing with the common vegetables of the day, although not much is known about their actual preparation as food. The most commonly mentioned vegetables were lentils, leeks, lotus, melons, gourds, garlic, asphodel (grown for its bulb), fava beans, chickpeas, fenugreek (ground as flour), garland chrysanthemum

(now popular in Asian cooking), cucumbers, onions, lettuce, and mallow. Egypt also served as a conduit for the introduction of watermelons from tropical Africa and, during the late Ptolemaic Period, for the introduction of rice, taro, and sugar cane from Trapobane (ancient Sri Lanka). Due to their dependence on specialized irrigation and cultivation techniques, none of the last three plants spread beyond the eastern Mediterranean until after Arab conquest.

The Greek occupation of Egypt under the Ptolemys radically altered the Egyptian vegetable garden, both with new introductions and in lasting terminologies. *Molókhe* or mallow (*Malva parviflora*), which was once so important to Greek cookery both as a green sauce and as an ingredient in complex recipes, also supplied leaves used like grape leaves for making dolmas. The Egyptians transferred the Greek name to a native wild plant now known as Jews mallow (*Corchorus olitorus*), which was similarly used in green sauces. It is still called *molkhia* in Egyptian Arabic. The use of the same name for plants of a different genus or species is one of the lasting ambiguities inherited from the ancients, who were more apt to lump vegetables together according to how they were used, as in the case of the Roman propensity for treating carrots, parsnips, and parsley root as *pastinaca*.

### The Vegetables of Ancient Greece and Rome

There are few surviving writings from the Greeks and Romans that do not mention food and vegetables in some manner. It is known from quotes and citations in works like the *Deipnosophists* of Athenaeus that many books on gardening and agriculture once existed but are now lost. Athenaeus himself lavished considerable attention on foodstuffs, none the least being vegetables. His interests ranged from toasted chickpeas (still a snack food in the Mediterranean) to the medical applications of beets and carrots as vermifuges or a good dish of cabbage to treat a hangover. He even cited the known varieties of lettuce, garlic, fava beans, and many other garden plants in an effort to differentiate which were the best from a connoisseur's point of view.

The surviving Roman work most easily accessible to the general reader is also by another connoisseur, an eccentric called Apicius, whose detailed recipes give specific hints about the role vegetables played in the haute cuisine of imperial Rome. For example, asparagus was baked in eggy casseroles called *patinae*, mallow was commonly added to barley soup, celery made a good stuffing for suckling pig, and turnips marry well with baked duck. There is also scattered advice on when to harvest certain vegetables, as in the case of stinging nettles, which only lose their prickly character when cooked or dried.

Many other works could be cited, such as Columella's *On Agriculture* and especially Pliny's monumental *Natural History*, but the medical writings of the imperial physician Galen are perhaps the richest in detail, since there is considerable commentary on the diet

of peasants and farmers and the sorts of vegetables they ate. The aristocratic tone and intended readership of most of the writings that have survived from this period do not provide the kind of firsthand observations one might expect from a true master gardener, although Pliny's eye was in fact well nuanced to such details—yet some of his botanical “facts” are obviously scrambled and second-hand. And while it is true Columella certainly knew how to run an estate, he was not the vegetable gardener.

Furthermore, aside from comments about asparagus and cabbage, Cato's treatise *On Agriculture* makes only passing reference to vegetables—be certain to grow them near cities. While this allusion does confirm the existence of well-organized market gardening, Cato's treatise is so loaded with ideology about salty Romanness (*Romanitas*) and the purity of certain rigorous lifestyles that any conclusions drawn from him must be done so with definite reservations. However, it is fairly clear from these and other ancient authors that quite a few cities had developed market gardening to a high degree and even specialized in the cultivation and export of vegetable produce to Rome and other large urban centers.

For example, Cyrene in present-day Libya was well-known in ancient times for its silphium, fragrant saffron, and a mild-tasting tuber now generally identified as taro. It was also the center for the export of the so-called wild artichoke (*Cynara cornigera* Lindl.), whose domestication was introduced early into Cyprus, Libya, and Carthage from the Levant. This handsome plant is depicted on surviving mosaics in the House of Dionysios at Paphos, Cyprus, and in a mosaic in the Bardo Museum at Tunis. The Roman farmers of Spain and Italy evidently adapted the novel idea of harvesting the flower bud as a delicacy to their local wild cardoons because the artichoke of the western Mediterranean is a subspecies derived genetically from the cardoon (*Cynara cardunculus* L.), not from a wild artichoke ancestor. Buds of the milk thistle, blessed thistle, and safflower were also similarly harvested and eaten.

The dissemination of the artichoke, or at least of the horticultural technology required to cultivate it for food, brings up the larger question of plant exchange during the height of the Roman Empire. Commerce flowed to and from the far-flung provinces in a manner only replicated by the European Union. Archaeology has indeed confirmed that foodstuffs moved quite easily from one place to another, with such exotics as rice turning up in sites in Germany and England. There is also indisputable evidence that, among the aristocracy at least, country life on the great estates attempted to imitate the court life of imperial Rome. Gardens excavated from villa sites have confirmed this.

On the local level, however, Mediterranean cuisine and Mediterranean vegetables were not readily assimilated among the general populace. Joan Alcock's study of food in Roman Britain (2001), based on overwhelming archaeological evidence, reached the conclusion that assimilation was selective, and it was this selectivity that

gave rise to the regional cookeries that eventually provided a link of continuity with the regional cookeries of the Middle Ages. This is also the growing consensus of archaeologists in other parts of Europe. Thus, the old saw that “the Romans introduced it” must be requalified, especially since quite a number of vegetables were cultivated in some regions long before the Romans arrived. Cabbage, especially the kales, originated in northern Europe, and in fact, the English words for kale and cabbage are Celtic in origin, as are the German words *Kabbis* and *Kohl*, not to mention the Latin *brassica* and *caulis*. This is evidence in itself that the vegetable exchange during Roman times was complex and two-way, with the Romans themselves learning new things from conquered peoples.

A broader look at Roman literature of all types is especially useful in drawing general conclusions about the state of vegetable gardening from that time. For example, Pliny parodied “gastronomic prodigies,” monster vegetables and fruits valued for their size alone. This would suggest that some market gardeners were well acquainted with horticultural practices based on careful seed selection, cold frame techniques, and the manuring of plants at critical periods of growth, much like the modern-day cult of the monster pumpkin or watermelon. There is also a great deal of information concerning value judgments about the role of vegetables in the diet and their cultural significance. Many Roman satires mention garlic as a food only fit for galley slaves and peasants or as something eaten only by soldiers going off to war (garlic heats up the body and therefore creates a warlike spirit). The general drift is that anything flavored with garlic is therefore rustic and unrefined and as much an antidote to poison as it is to the consuming flames of love (what sweet kiss is not withered by the scorpion sting of garlic breath?). Likewise, fava beans are eaten by jurymen in order to stay awake during trials, their noisy flatulency providing an echoing thunder of divine approval or of legal derision.

The most commonly mentioned vegetables in Roman literary sources include many still known, although in shape and habit they probably did not resemble modern varieties. The list includes turnips, radishes, rocket (arugula to American grocers), leeks, lentils, lettuce, orach, Old World gourds (eaten young like zucchinis), cabbage, onion, peas, chickpeas, fava beans, cucumbers, asparagus, cowpeas, beets, beet chards, sprouting broccoli, watermelon, garlic, mallow, dock, chickling vetch, and blite—otherwise known as purple amaranth (*Amaranthus lividus*).

A number of scholars have taken the liberty of translating *blitum* (blite) as spinach (Gowers, 1996), and this has greatly added to the confusion about the culinary history of spinach because *blitum* is not true spinach. However, something called *barbaricum bliteum* (barbarian blite) also surfaces in Roman literature. This is either true spinach as cultivated by the Armenians and Persians or else good-king-henry, so important to the ritual cookery

of the ancient Gauls—the leaves of both plants are similarly shaped. In any case, this mystery vegetable was considered insipid eating and was equated with crudeness and stupidity (insipid people were people who lacked “flavor”).

Some of these vegetables also carried a great deal of symbolic baggage, especially in connection with religious cults. Mallow (*molóche*) was considered one of the purest sacrifices for Apollo Genétor at Delos, and Pythagoras himself was said to have lived on it as part of his vegetarian dietary regime because it “washes” the stomach.

Lettuce was associated with the gruesome death of Adonis, the prepubescent lover of Aphrodite, who hid among lettuce before he was gored to death by a wild boar. Thus lettuce was associated with male sterility, effeminacy, and cowardice, and generally was viewed as a suppressant of sexual performance (Detienne, 2000). Gardens of Adonis were planted in pots or baskets during the heat of summer and then allowed to die prematurely on the roofs of houses during the feast of Adonia (19 July during the Roman Empire) as symbolic evidence of the boy’s sexual prowess, which produced no “seed” or fruit. Significantly, these little gardens consisted of barley, wheat, lettuce, and fennel, each plant highly symbolic of some aspect of fertility yet a total inversion of what was understood to be garden abundance.

Interestingly, a distinctive lettuce dedicated to Gausus (the Cypriot Adonis), and later known as “Cyprian” during the Byzantine period, was discovered in a Serbian monastery by the U.S. Department of Agriculture in the early twentieth century and is preserved in several American seed banks. It is physically similar to the pointed-leaf lettuce depicted in the medieval *Tacuinum Sanitatis* (Arano, 1976) of the eleventh-century Syrian Christian physician Ibn Botlân. By virtue of this continuity, at least in form and appearance, Cyprian lettuce is a true heirloom variety, a category of vegetable that will be dealt with later in this discussion.

### Vegetables in the Early Christian Period

The early Middle Ages is a murky period for the study of vegetables, but a copy (in the Austrian State Library at Vienna) of the *Codex of Dioskorides* dating from 500 to 511 C.E. is illuminated with pictures of plants. The drawings are fairly accurate and convey the important physical characteristics of the vegetables and herbs shown. Thus it is possible to determine that a leek on folio 278 belongs to the Kurrat Group, an ancient type of salad leek mentioned earlier and still grown in the Near East.

The *Codex of Dioskorides* is medical in nature, dealing with the health and dietary aspects of the plants discussed. For a horticultural companion, the *Gheoponika* of Kassianos Bassos, a tenth-century reworking of several older agricultural treatises, provides rules for the cultivation of garden vegetables, thus offering some insights into the seasonal food cycle, both horticultural and culi-

nary, in the old Byzantine East. More specifically, the role of the *Gheoponika* in the provisioning of Constantinople with fresh vegetables has been studied by several historians, most importantly by Johannes Koder (1993). When taken together with the *Book of the Eparch* (prefect of Constantinople) regulating merchants and guilds during the reign of Leo VI (886–912), a relatively detailed picture of market gardening falls into place. It is perhaps significant to note that by the 1100s many villages in Bulgaria were given imperial privileges that freed them of military duty in exchange for producing food for the court. It is for this reason that the Bulgarians have long been called the gardeners of the Balkans, a status they maintained even under later Ottoman rule.

In the West, the eighth century *Capitulaire de villis* of the Holy Roman Emperor Charlemagne is quite valuable for its references to gardens. For example, the *ravocaulos* of that document is believed to refer to a variety of kohlrabi. However, the most priceless garden record is a parchment drawing of the garden plan of the Cloister of St. Gall in Switzerland surviving from the early 800s. It provides a detailed look at how the Roman kitchen garden became transmogrified into a source of both food and medical plants. Sixteen plants are discernible on the plan, including cucumbers, melons, cowpeas, bottle gourds, and smallage (celery resembling parsley). Most important, they are organized into rectangular raised beds. This is one of the earliest references extant to this common garden practice, but it was not unique.

The *Hortulus* of Walahfrid Strabo, abbot (from 838 to 849) of the Cloister of Reichenau on an island in Lake Constance, makes reference to a similar number of plants, again arranged in raised rectangular beds. Strabo’s Latin poems about his garden discuss the uses of both herbs and vegetables and is the oldest surviving source on gardening written in Europe during the Middle Ages. Most interesting of all, archaeological exploration of the abbey site has revealed that it was constructed from the recycled ruins of an abandoned Roman villa and that the layout of the garden more or less followed the outlines of the ancient one. The implication is that the Roman gardening tradition maintained by the wealthy during imperial times did not fully disappear at the outset of the Middle Ages. Many estate gardens disappeared completely due to wars and pillaging, but in some regions they simply became fewer in number and passed into non-Roman hands (Percival, 1976). Château Ausone near Saint-Emilion in Bordeaux is a famous example of this continuity, although its fame rests on wine not gardens.

The archaeological link is not as clear when it comes to the vegetables themselves, since botanical residues, especially seeds, impose certain limitations on what can be retrieved for science. A carrot seed is indistinguishable from a wild carrot seed and will not tell how the root was shaped or even its color. Unfortunately, seeds are mostly what one has to work with from medieval sites, although some inferences can be revealing. Cucumber seeds show

up in Polish sites in the 900s, thus establishing a bottom line for a vegetable much associated with Polish national cookery. Carbonized fava bean plants from North Germany from the same period reveal that, after the beans were harvested (as winter fare), the plants were used as straw in barns. Seeds, however, do help untangle dates of introduction, and one thing that scholars have learned from medieval archaeology is that the vegetable world was not static, as historians have led us to believe in the past.

The broad, flat fava bean, which is the preferred sort for modern cookery, did not appear until the 800s in Spain. This is only one example of vegetable breeding (probably through highly controlled selection) that took place during the Middle Ages, although innovation was indeed slow by present-day standards. Some agricultural historians have suggested that it was the Arabs who created these new types of vegetables—the cauliflower, for example. What can be documented from surviving Arab literary sources is rapid dissemination, but the westward movement of plants in general and vegetables in particular was far more complex than hitherto presumed and remains an area of research ripe for future exploration.

### Vegetables and the Arab Diaspora

The agricultural historian Andrew Watson has long promoted the idea that an agricultural revolution took place under early Islamic rule in the eastern Mediterranean, a revolution that was carried westward into North Africa and Spain (Watson, 1983). This has important implications for the movement of vegetable plants. However, other scholarship has questioned this thesis. There is growing evidence that the revolution was already taking place during the late Byzantine period and that it consisted of newer ways of irrigating land and reclaiming marshes so more intensive forms of agriculture could be undertaken. Without entering the question of who invented what, two critical points are undeniable: the technology came out of Persia and South India (the vast irrigation systems in Sri Lanka were well known even to the Greeks), and its spread westward was made possible by the political stability that Arab conquest brought to the regions under its control. It is easy to point to the concentration of wealth in bright spots such as Syria (Damascus and Baghdad in particular), Egypt, and al-Andalus in Spain, but there was an economic implosion in other parts of the newly formed empire. The family papers of the Ibn'Awkal merchants of eleventh-century Egypt reveal a great deal about industrial crops like Egyptian flax or high-profit goods like black pepper, indigo, and sal ammoniac, but information on common garden vegetables is rather limited. That is, unless one looks at medical literature and cookery books.

The most heavily used culinary source is also one of the oldest: the *Kitab al-tabikh*, otherwise known as the Baghdad cookery book. It was written down in 1226, although internal evidence clearly indicates that the material was compiled from several much earlier sources, some

of which were not Arabic. This ambiguity is one of the difficulties in using cookbooks to pinpoint the introduction of new vegetables. But that said, there are other Arabic cookery manuscripts equally rich in detail surviving from the Middle Ages, such as the *Manuscrito Anónimo* of Moorish Spain, and all of the recipes no matter what the source are fairly clear about the role vegetables played in the diet of the times.

There is certainly no ambiguity in the Baghdad cookery book about the use of eggplants and no doubt at all that the sort discussed had dark black skin (there are directions for removing it). The book also makes ample reference to fava beans, cardoons, rhubarb, leeks, the ridged cucumber (Armenian snake melon), carrots, gourds, taro, cultivated purslane, turnips, sweet fennel, and spinach. There are also references to a form of cabbage commonly translated into English as cauliflower. Without a picture, one cannot be sure (it could be a type of broccoli), but since true cauliflower evidently evolved in the Dead Cities region of northwestern Syria, it is quite likely that this luxury vegetable migrated during the early 800s with its growers when they resettled elsewhere—a small group of those Syrian Christians emigrated to the Karpasia district of Cyprus, where cauliflower was first observed by pilgrims to the Holy Land later in the Middle Ages. The cauliflower is not mentioned in European scientific works until specimens are discussed by Dodonaeus in 1560. By that time Cypriot seed was being exported to northern Europe via Venice.

One is also treated with a rich array of vegetables in another work called *Kitab Wasfal-At'ima al-Mu'tada* (Description of Familiar Foods) written in 1373. Of particular interest is the differentiation of several types of leeks, indicating not only distinct varieties but also distinct culinary uses at different stages of development—indirect evidence of a highly evolved sense of market gardening. Four sorts of leek are mentioned: the vegetable leek (*kurrath baql*), the Nabatean leek, the table leek, and the Syrian leek. The first is not a variety but rather a spring leek, young greens similar in character to Chinese garlic chives. The Nabatean leek may be equated with the modern salad leek of Iraq, a member of the Kurrat Group, short in height and rather deep-rooted. The table leek is a blanched leek similar to the Catalan Calçot onion, and indeed the cultural technique of burying them in deep trenches may be the same. The Syrian leek is the *kephalotón* of medieval Cyprus, a Greek word derived from Syrian *quaflot*, a leek with an unusually large bulb. This plant is the genetic ancestor of the modern elephant garlic. Under the name *Porrum Syriacum*, it was first illustrated in European botanical literature by Tabernaemontanus in 1588.

Arab books dealing with cookery exhibit an undeniable passion for elegant preparations, even with simple vegetables. But such food was the privilege of the aristocratic few, and the wealth that sustained that lifestyle was soon to fade with the economic upheavals caused by the

Crusades. Until the late twentieth century, historians have greatly underestimated the exchanges that took place after the establishment of Latin footholds in the Levant and Byzantium or the role of large Christian minorities that persisted in Egypt and Syria during the early Muslim period.

The Nestorian or East Syrian Church, which spread into Persia, established strong trading communities in China and Malabar as well as in Cyprus, where the Nestorian Lakhan family became extremely powerful based on trade in medical aloes. One line of trade and plant exchange went through Tabriz in Persia overland to the Caucasian kingdom of Georgia and the Greek Empire of Trebizond on the north coast of modern Turkey, all to circumvent the Arabs. That this Black Sea entry was an important route for the movement of Asian food plants westward may be inferred from an eleventh-century Byzantine reference to the “citrons” of Anatolia, a variety of lemon introduced via Georgia and Armenia and still preserved in Georgian botanical collections. Eggplants also followed this route.

European contact with foods of the Arab world was not limited to the crusading troops that went to the Holy Land and returned. The Latin Kingdom of Jerusalem (1099–1291), the Principality of Achaia (1205–1430), a French feudal state established in Greece with its capital at Mistra, a Catalan principality centered on Athens, various Venetian and Genovese ports, and the sister kingdoms of Cilicia (1080–1375) in Asia Minor and on Cyprus (1192–1489) were all characterized by colonial aristocracies with highly orientalized foodways.

The last kingdoms, especially that of Cyprus due to a Papal Bull, served as conduits for the spice trade with the Muslim world. In the case of Cyprus, the kingdom lent its name to an international style of cookery mentioned in numerous medieval cookbooks. More important, the intermarriage of wealthy Latins in the Levant with European nobility, particularly with families in Aragon and in northern Italy, brought to Europe a constant influx of personal cooks, gardeners, and retainers schooled in eastern Mediterranean ways. It is not surprising that some of the earliest references to exotic vegetables like eggplants, cauliflowers, okra, and numerous sorts of Near Eastern melons show up in late medieval Italy.

### Vegetables in the Renaissance

The *Carrara Herbal* (British Library, Egerton MS 2020), created sometime before 1403, was one of the first late medieval herbals to depict plants and vegetables accurately, although it may have been based on a now lost Byzantine prototype. Such illustrated handbooks of health, as well as numerous herbals, offer a rich visual record of the sorts of vegetables deemed worthy for the table in that period. The beautiful gardens witnessed by travelers through the Latin East were now replicated in Italy but with the goal for reattaining a glorious Roman

Hands holding a variety of vegetables: beet chards, carrots, turnips, spring onions, and radishes. © CRAIG LOVELL/CORBIS.

past. The Italian pleasure gardens of this period so impressed Casimir the Great of Poland that he installed one in Cracow during the 1360s, complete with cold frames for forcing Mediterranean vegetables. In short, the vegetable garden once again becomes an object of status.

The discovery of printing, followed quickly by the discovery of the New World and the heady harvest of its vegetable riches, only accelerated a quest for new and exotic things to ornament the gardens of the rich and powerful. Tomatoes, peppers, potatoes, sunflowers, beans, sweet potatoes, new sorts of pumpkins, and a new kind of wheat called maize fill the pages of botanical treatises and plant books of the period. The 1500s may be characterized as a century during which botanists attempted to organize the vegetable world into some type of scientific order, although that “order” by modern standards was quite chaotic. For example, a confusing observation is that the Jerusalem artichoke from North America (not from Jerusalem and not an artichoke) is known as *Flos solis Farnesianus* (Farnese sunflower) in reference to the fact that the gardens at the Villa Farnese in Rome provided several botanists with the first known specimens. Sorting out such conflicting nomenclature has plagued garden historians ever since.

However, botanical gardens were established in this century, the first in 1545 at the University of Padua, and some of the greatest botanical works of the Renaissance

were issued during this era, especially those devoted to cataloging the gardens of such important plantsmen as Conrad Gesner in Switzerland (1561), Georg Fabricius in Meissen, Germany (1569), and Camerarius in Nürnberg (1588). All of these books contain valuable woodcuts depicting vegetables, and many medieval favorites like skirret (*Sium sisarum*) and monk's rhubarb (*Rumex patientia*) are shown for the first time. Vegetables also figured prominently in Renaissance art and paintings, especially the still life genre. Among the most whimsical vegetable compositions are those by the court painter Giuseppe Arcimboldo (c. 1527–1593), who used vegetables and fruits to create faces and other conceits.

The most significant body of literature, however, was the garden guides that discussed not only specific vegetable varieties but also how to grow them. The French work known as *L'agriculture ou la maison rustique*, first published in Latin (1535) by the Paris printer Charles Estienne, was soon translated into most major European languages. Marco Bussato's *Giardino di agricoltura* (Venice, 1592) was also extremely influential, as was Johann Coler's *Oeconomica ruralis et domestica* (Wittenberg, 1597). The great classic, however, was Oliver de Serre's *Théâtre d'agriculture* (Rouen, 1600), which became a standard garden book for much of the next century. This great outpouring of garden knowledge was capped in many ways by the lavishly illustrated *Hortus Eystettensis* assembled by Basilius Besler in 1613 for his patron plant collector, the bishop of Eichstätt in Bavaria. Not only did the good bishop own prize specimens of rare eggplants, balsam apple (*Momordica balsamina*), tomatoes, and domesticated asparagus, his potted prickly pear cactus from the New World required a wooden superstructure to hold the monster plant in place.

### Vegetables in the Baroque Period

The seventeenth century witnessed a revolution in botanical science and the proliferation of books devoted to illustrating plants and vegetables from many parts of the world, including new introductions from Asia and the Americas. Francisco Hernandez's *Nova Plantarum* (Rome, 1651) was devoted almost exclusively to the foods of Mexico and included native names for the plants. His woodcut illustrations offer a priceless look at the characteristics of common vegetables then grown in New Spain, including the lowly miltomatl or tomatillo (*Physalis ixocarpa*) now popular in Southwest American cooking. Other books containing strange designations like *Pomum amoris majus fructu luteo* (large yellow fruited love apple or, more simply, yellow tomato) remind one how much lack of order prevailed in the scientific naming of newly discovered vegetables and how much has changed since Linneaus imposed order on the world of plants in the eighteenth century. Names like *bamia Aegyptiaca* (Egyptian okra—*bamya* is actually a Syrian word) of one author might become “ladies’ fingers” of the next. Likewise the *lactuca hispanica* (Spanish lettuce) of one author was the

*Cos* or Roman lettuce of another, the names more often than not reflecting the source of seed rather than the true origin and history of the vegetable. One of the most fashionable cabbages of the period was the so-called *Brassica tophosa*, better known as black Tuscan palm tree kale, “re-discovered” by American seedspeople under the new moniker “dinosaur kale.” The penchant for fanciful names has not changed.

If a generalization can be made about the seventeenth century, it is that the rare and exotic vegetable of the previous century gradually became the daily fare of the urban middle class by 1700. Plant breeding, especially in Holland, brought many new sorts of vegetables onto the market. Named varieties of potatoes, carrots, celery, chicory, peas, and turnips soon proliferated in kinds and colors. Added to this roster were newly discovered Asian foods, like Malabar spinach (*Basella alba*), introduced from Java in 1688. Handbooks on plant breeding were even published, one of the earliest in English being Walter Sharrock's *History of the Propagation and Improvement of Vegetables* (1660). From this time on, the vegetable undergoes a steady refinement with emphasis on greater delicacy of flavor, more beautiful shape, and increasing tenderness.

Much of this was directly connected with shifts taking place in cookery, especially the use of vegetables in sauces and elaborately prepared dishes. Vegetables were also given ornamental value with paring knives, so turnips feathered out into birds, carrots unwound into golden fish, and the cookbooks of the day are full of illustrations showing how to do this. Most notably, however, the vegetable became a prized market commodity; growing of vegetables, a respectable line of work for the honest laborer; and period depictions of market scenes never fail to convey the impression that only the best has been laid before the eye.

Aside from shifts in cookery, the virtues of country life and the pursuit of its simple pleasures helped elevate vegetable gardening as a worthy and genteel pastime. Jan van der Groen's *Den Nederlandtsen Hovenier* (Amsterdam, 1669) was extremely influential in this respect, as were Nicolas de Bonnefon's *Les delices de la campagne* and *Le jardinier françois* in France. All of these works were translated into several languages and included specific discussions of vegetable varieties and cooking tips. Under fava beans, for example, Bonnefon recommended several different methods of preparation, including fricassees like peas or boiled plain with slices of bacon, noting that fresh green savory went “marvelously well” with any fava bean dish.

Not the least important, from the standpoint of vegetables, was John Evelyn's *Acetaria: A Discourse on Sallets* (London, 1699), which discussed most of the popular types of vegetables of the day, especially ways to employ them raw or semicooked in salads. Of earth chestnuts (*Bunium bulbocastanum*) he remarked: “the Rind par'd off, [they] are eaten crude by Rustics, with a little Pepper; but

are best when boil'd like other Roots, or in Pottage rather, and are sweet and nourishing."

### Vegetables in the Enlightenment

The idea that vegetables recaptured the original wholesomeness of Eden became an underlying theme for many of the more offbeat cookbooks of the eighteenth century, with *Adam's Luxury and Eve's Cookery* (London, 1744) considered one of the most typical. The underlying philosophies expressed in these books may be said to represent the intellectual forerunners of true vegetarianism, which was indeed practiced in colonial North America by the so-called White Friends, a group of Quakers who wore clothing of unbleached cloth. The most highly organized vegetarians in early North America, however, were the Bible Christians, who expanded from England in 1816. Martha Brotherton's *Vegetable Cookery* (London, 1833) became the dietary handbook for this group.

The European penchant for country life was quickly transferred to England during the 1600s and from there to colonial America. Doubtless it achieved its American apotheosis in such famous estates as William Penn's "Pennsbury Manor" along the Delaware River, Thomas Jefferson's "Monticello" in Virginia, William Hamilton's "Woodlands" near Philadelphia, and Charles Carroll's "Mount Clare" in Baltimore. Jefferson's personal garden account book, published by the American Philosophical Society in 1944, remains a lasting testimony to the central role that kitchen gardens—and vegetables in particular—played in this manorial lifestyle.

It was on such estates as these that many of the Old World exotics were first introduced to North America. Charles Norris of Philadelphia, for example, is known to have raised black-skinned eggplants, since a letter survives from 1763 imploring him for seed. Many of the most popular vegetables of this period can be found in Philip Miller's *Gardener's and Botanist's Dictionary* (London, 1759), and remarkable as it may seem, some of Miller's vegetables are extant, among them red celery, Spotted Aleppo and Silesia lettuces, spinach beets, and domesticated sea kale.

### The Vegetable in the Nineteenth Century

The Industrial Revolution in England and Europe created the need for a new type of gardener and, indeed, new sorts of vegetable varieties. Market gardening had always existed to some extent in and around urban centers, but the huge new concentration of landless workers packed into the cities meant someone else would have to act as a surrogate kitchen gardener to supply their tables. Thus vegetable horticulture underwent rapid specialization with growers focusing on such basic food crops as cabbages and onions, or turnips and potatoes.

New demands were placed on vegetable breeders for vegetables that would travel well and that gave a good appearance even after rough handling. The old-time requirements of the country kitchen gardener for vegeta-

bles that dried or pickled well were overthrown by cold frame and hot-house horticulture that could deliver such tender things as fresh peas and lettuce all winter. Furthermore, most of the old medieval vegetables like skirrets, rampion, orach, sow thistle, and nettles dropped out of mainstream diet and by the mid-nineteenth century were largely associated with rural poverty, those "rustics" mentioned by Evelyn in his treatise on salads. So thorough has industrialization distanced the consumer from the *horta* of old traditional northern European diet that the wild greens of Mediterranean culture, indeed any unusual food plants from Asia or Africa, are embraced as an antidote to a diet adrift of its "natural soul."

The two bibles of nineteenth-century American kitchen gardening are arguably Bernard M'Mahon's *American Gardener's Calendar* (Philadelphia, 1806) and Fearing Burr's *Field and Garden Vegetables of America* (Boston, 1863). Both of these works were reprinted in the twentieth century because they contain long, valuable lists and detailed descriptions of many nineteenth-century vegetables. Burr even included small woodcut illustrations. M'Mahon's book is a cultural bridge with the past, for it contains much on the old types of vegetables still eaten by traditionalists of his day. His is also a book written for the person who gardens, in particular a person who employs a staff, thus his vegetables fall into that category of food destined for genteel tables. Fearing Burr's book was quite another sort.

Burr's primary interest was to catalog the best commercially available vegetable varieties so gentlemen farmers and market gardeners would be guided in their selection of the best seed for the best investment. The book was arranged like a scholarly encyclopedia, and it was not cheap, two points against it from a farmer's standpoint. Its New England stodginess was quickly overtaken by Peter Henderson's *Gardening for Profit* (New York, 1865), an inexpensive handbook that became a best seller and the blueprint for true truck farming. Henderson was a seedsman, and he was not blind to the fact that small-scale farming for urban markets would require yet another type of vegetable; indeed, his book marks the birth of the so-called commercial vegetable grower.

Henderson's effect on vegetable breeding was immediate, and nowhere in the United States did it manifest itself more than in the explosion of newfangled high-profit tomatoes. The Paragon tomato was introduced in 1870 along with the canning jar of the same name—the connection was not coincidental. The leading tomato breeder of the time was Alexander Livingston (1822–1898) of Ohio. His Acme tomato (1875), Golden Queen (1882), Beauty (1885), and Stone (1891) are still grown and are considered among the classics of American commercial garden vegetables. But Livingston was only one of a number of seedspeople actively engaged in creating newer and better vegetables for the market. Perhaps the dean of them all was W. Atlee Burpee of Philadelphia, who even went so far as to offer large monetary

rewards for backyard discoveries worthy of commercialization. Many of Burpee's best vegetable introductions came from housewives and farmers who happened to have an eye for the unusual, of which the Montreal Market Melon is a prime example. Burpee's sense of marketing was also shrewdly sophisticated, because he hired Sarah Tyson Rohrer, owner of the Philadelphia Cooking School, to create a cookbook called *How to Cook Vegetables* (Philadelphia, 1891), thus insuring that even the most helpless beginner would feel confident in buying his seeds. After all, they received the cookbook as a bonus.

The second half of the nineteenth century witnessed a large increase in the number of vegetables developed solely for manufacturing purposes not only in the United States but in Europe as well. In France, the tiny cornichon pickles were introduced in the 1880s. In England, the Marrowfat pea became the ubiquitous pea of the canneries, both as a canned vegetable and as pea soup. Whole communities grew up around the production of one vegetable. In Germany, Zittau became famous for its monster onions and Tetlow for its dwarf turnips; Poitou in France became famous for its golden leeks. In the Austro-Hungarian Empire, at Znaim in what is now the Czech Republic, a pickling industry was established in 1852 based entirely on the Znaim cucumber, a mutation of a cucumber brought from Asia in 1802. This pickle capital of central Europe remained in business until 1945, when it collapsed under ethnic cleansing. Today the Znaim cucumber is extinct.

The need for fresh breeding stock to supply growers with newer and better varieties of plants lay behind the establishment of several experimental gardens in the late 1800s. The most famous was at Crosnes (Seine-et-Oise) in France, a place-name now attached to a tuberous vegetable (*Stachys affinis*) from China first trialed there in the 1880s. The heads of that garden were Auguste Paillieux (1812–1898) and his assistant Désiré Bois. The two of them coauthored a garden classic known as *Le Potager d'un curieux* (Paris, 1885), and Bois later published his own masterwork, *Les Plantes alimentaires* (Paris, 1927). These men were responsible for a large number of new vegetable introductions, and they were interested as well in their histories. They valued the research of such botanists as Emilii Bretschneider, whose history of plant exploration in China (1898) remains one of the milestones of nineteenth-century horticultural writing. They were also keenly aware of the value of biodiversity.

The greatest collector of vegetables and edible plants in general specifically for their genetic interest was Nikolai Vavilov (1887–1943) of Russia. The Vavilov Institute, founded at St. Petersburg in 1905, became a model for similar gene banks established in other countries, including the United States. Vavilov's collections gathered from all parts of the world are considered priceless, and they have taken on much greater importance since the development of hybrids and genetically engineered foods.

In the past the hybrid vegetable was viewed as a worthless mule, and most growers disdained them because they were not fixed in their characteristics, thus they would not grow true from seed. A revolution took place in this thinking during the 1940s as seed companies began to promote the benefits of controlled crosses to yield vegetables with specific traits. Such plants are known as F1 hybrids, the label standing for "first generation." This concept has further evolved with the idea that the precise genetic mix to create that plant may be patented and thus owned in perpetuity. Genetic engineering has added one more element to the mix: traits borrowed from near species or from other life-forms to create vegetables that would not have occurred in nature. This type of vegetable dominates agribusiness, but it has also come under attack from many quarters under the moniker of "Frankenfood" (a word combination of "Frankenstein" and "food").

The primary argument against the hybrids is that, since seed cannot be saved, growers are forced to purchase new seed each year. For large-scale farmers, this increases the debt side of the ledger at the cost of seed-saving convenience. Another argument is that hybrids on the whole lack the same vigor as open-pollinated plants, that there is some long-term genetic decline at play. The patented vegetable has been criticized on moral grounds (who owns Nature?) and because it is easy to circumvent the patent by creating renegade varieties with slightly different genetic compositions. Furthermore, the ownership issue resembles the sort of complex economics of old tithes and quitrents that eventually changed medieval agriculture from a tenant system to serfdom. This New Feudalism is based not on class privilege but on farms mortgaged to banks, fertilizer companies, and seed suppliers.

While the pros and cons of these arguments are primarily limited to the farming side of the equation, it is an issue that ultimately affects the consumer and the price of vegetables on the shelf. These issues are also more polarized in developed countries like the United States than in Africa, Asia, or Latin America, where small-scale farming is the norm, and the economics of farming are different and are not necessarily based on cash flow or cash crops. However, the financial success of hybrids, patented varieties, and genetically engineered food is predicated on cheap oil for transportation, not to mention the chemical by-products of oil translated into herbicides and pesticides required to maintain these specialized vegetable crops. Oil, not politics or environmentalism, may ultimately determine the future of such vegetables. But there is also another revolution taking place. It is known as artisanal agriculture, its technology is increasingly organic, and it is based on open-pollinated vegetables, many of which are also heirloom varieties.

### **The Heirloom Vegetable and the Ten-Acre Farm**

The discovery of vitamins and the role they play in human nutrition raised the status of the vegetable from an

adjunct to the meal to a much more centralized role. When it became clear that legumes could deliver much of the same nutritional value as meat, a new look at all sorts of vegetables seemed to be in order. On hindsight, the appearance of Eleanor Sinclair Rohde's *Uncommon Vegetables* (London, 1946) and John Organ's *Rare Vegetables* (London, 1960) should have served as warnings that a shift was taking place in the food world and that this shift was the harbinger of something new. Several elements appear to have converged and to have begun working in conjunction with one another.

The first was a general setting of rapid economic growth, especially in the 1980s, and the flow of some of this new-made wealth into dining out. The second was the mainstreaming of vegetarianism and more broadly of healthy lifestyles, which placed new demands on the market (and on restaurants) to come up with a more challenging and nutritionally satisfying range of vegetable choices, although not necessarily inexpensive choices. The third was the American Bicentennial in 1976, which spawned a renewed look at historical foods and foodways and which gave rise to a number of grassroots organizations devoted to studying and preserving foods of the past. The most important plant organization, and one with enormous continuing influence, is Seed Savers Exchange in Decorah, Iowa, the high temple of what is known as the heirloom vegetable.

The fourth and perhaps the most significant development was the growth of small or artisanal farms devoted to supplying high-end urban markets with the vegetables demanded for a new American cuisine variously styled California cuisine and championed by such activist restaurants as Chez Panisse in Berkeley, California, and the White Dog Café in Philadelphia. The core concept of California cuisine was the use of locally grown food products with an emphasis on freshness, originality, and organic horticultural methods. This type of model could be replicated anywhere in the country, and thus a real interest in heirloom vegetables was born.

The heirloom vegetable is a variety that has been handed down from the past. It may be an old commercial variety like Conover's Colossal Asparagus (1863), a garden classic like Victoria Rhubarb (1837), or a symbol of American gardening genius like the Brandywine tomato (1889). Whatever their role, these are plants that have been preserved more or less intact since they were developed. Their historical and cultural genealogies may be impressive, and this alone appeals to many people who sense a loss of cultural identity and who are looking for a means to recover their "natural souls." Native American heirlooms are extremely potent in this regard.

From an economic standpoint, the heirloom vegetable is free of the ownership issues inherent in hybrid, patented, and genetically engineered food. The heirloom belongs to the community, and an exchange of this food (as well as its seeds) is viewed as a strong link in the commonsality of people and a link with nature, especially

since the plants are pollinated by natural means out under the sky. On a less philosophical level, heirloom vegetables were developed to meet the agricultural needs of specific soils and environments and therefore do not require the same economic investment in fertilizers and insecticides as hybrid varieties. They are also strengthened by an inherent genetic diversity lacking in hybrid sorts—a built-in mechanism to prevent massive crop failure. This appeals to organic growers, and the surprisingly rich flavors of plants raised in this manner have gained many converts in the food community at large. Politically, the heirloom vegetable represents an alternative to the type of market control and genetic expropriation associated with agribusiness. In developing countries, this means local control of local food resources, a theme championed by the Food and Agriculture Organization of the United Nations.

When the astronauts first set foot on the moon, they looked back to behold a blue orb in the darkness of space. That view changed humanity, because it said as no words could express that Earth is indeed an Eden and perhaps, for all its vicissitudes, our only reward. The philosophies that have guided us in the past are seriously challenged. While it is true that vegetables are not perceived by humans to react to pain, fear, or anxiety and while they do not have red blood, who is to say they are not our protectors?

**VEGETARIANISM.** The dietary practice and philosophy of vegetarianism dates back to the views of Pythagoras in the fifth century B.C.E., as well as to religious practices associated with Hinduism, Janism, Zoroastrianism, and Buddhism. Historically, support for a vegetarian lifestyle has been grounded in both health and ethical and moral arguments. However, in the United States and Canada health arguments have dominated, and ethical and moral arguments typically have taken a lesser role. While many people become vegetarians because of concern for the treatment of animals raised in factory-like conditions, North Americans more commonly become vegetarians because they believe that it will help them lose weight, have more energy, or ameliorate such health conditions as high blood pressure or heart disease.

While the percentage of North Americans practicing vegetarianism has remained rather consistent at about one percent of the total population (and about 5 to 6 percent in the United Kingdom), social acceptance of this lifestyle increased dramatically in the late twentieth century. In large part, recognition by medical and nutritional authorities that vegetarian diets can be healthful and even desirable when appropriately planned has led to the legitimacy of vegetarian diets and to fewer fears regarding nutritional deficiencies. While the increasing scientific and cultural acceptance of vegetarian diets has not led to a greater percentage of the population adhering to vegetarian diets, more people are experimenting with "semi-vegetarianism," adding more meatless meals to their weekly menus.

### Varieties of Vegetarianism

A wide range of dietary practices falls under the rubric of "vegetarianism." People who practice the strictest version, veganism, do not use any animal products or by-products. They do not eat meat, poultry, or seafood, nor do they wear leather or wool. They avoid foods that contain such animal by-products as whey and gelatin and do not use products that have been tested on animals.

Other vegetarians limit their avoidances to food. For example, ovo-lacto vegetarians consume eggs and dairy products but not meat, poultry, and seafood. Ovo vege-

tarians do not consume dairy products, and lacto vegetarians consume dairy products but not eggs. Semivegetarians occasionally consume some or all animal products and may or may not consider themselves vegetarians. Studies suggest that semivegetarians outnumber “true” vegetarians by about four to one.

These terms define the various types of vegetarians by what they do not consume. Consequently, many vegetarians are concerned that nonvegetarians view vegetarian diets as primarily prohibitive and restrictive. They emphasize that following a vegetarian diet often leads people to consume a wider variety of foods than many meat eaters do, as vegetarians often include a wider range of fruits, vegetables, grains, and legumes in their diets.

### A Brief Historical Perspective

Vegetarianism arrived in the United States in the early 1800s as primarily a religious practice associated with the Bible Christian Church of Philadelphia. The church’s leader, William Metcalfe, advocated abstinence from meat as a form of spiritual temperance. In 1830 the Bible Christian Church hired Sylvester Graham, who had been studying medicine in Philadelphia, as a temperance lecturer. Graham soon branched out on his own, turning elements of a religious philosophy into a more secular set of practices in which he advocated abstinence from alcohol, sex, coffee, tea, spices, and of course meat.

Graham’s philosophy was rooted in a deep distrust of the emerging industrial revolution of the 1830s and 1840s. He expressed concern that the marketplace was supplanting the role of “hearth and home” in developing moral character and stressed the importance of individual efforts to restore a moral balance in an increasingly chaotic social world. With Metcalfe and such vegetarian advocates as William Alcott and Russell Trall, Graham helped form the American Vegetarian Society in 1850. Many early suffragists and abolitionists, such as Susan B. Anthony, Lucy Stone, and Horace Greeley, attended the early meetings of this organization.

The vegetarian legacy continued with the efforts of John Harvey Kellogg, who developed cornflakes in 1894. The Seventh Day Adventist Church hired Kellogg in the 1870s to run its Battle Creek Sanatorium, where popular treatments included exercise, hydropathy (water cure), and a vegetarian diet. The Seventh Day Adventist Church continued to endorse and promote vegetarian diets in the twenty-first century, although it did not require its members to adopt them.

Interestingly, although early vegetarianism was strongly associated with religion (first with the Bible Christian Church and then with Seventh Day Adventism), vegetarianism has been primarily a secular rather than a spiritual practice in North America. Even the early vegetarians were encouraged to adopt vegetarianism as a means to good health that would enhance their individual capacities, including their capacity to experience the Divine,

Early eighteenth-century engraving of Benjamin Lay, a Quaker vegetarian and hermit in Pennsylvania. Lay and other Quaker vegetarians known as “White Friends” (they wore only undyed cloth) were heavily influenced by Thomas Tryon’s *The Way to Health* (London, 1683). Tryon’s discourse contained material on Pythagoras and his vegetarian philosophies. Later editions were expanded with recipes for seventy-five “noble dishes” prepared without “eating flesh and blood.” Lay is shown holding Tryon’s book in his hand. ROUGHWOOD COLLECTION.

and vegetarianism has rarely been promoted as a spiritual path in and of itself. Consequently, despite its historically religious underpinnings, the health aspect of vegetarianism has predominated in the United States and Canada.

### Characteristics of Contemporary Vegetarians

While vegetarians probably exhibit more differences than similarities, researchers have discerned several patterns regarding their social backgrounds and statuses. Vegetarians tend to come from predominantly middle-class backgrounds, and a substantially smaller percentage comes from lower social classes. This can be explained by the fact that people who have less money view meat as desirable and associate it with upward social mobility. Therefore, when they have discretionary income, they are likely to use it to purchase meat products. In North America meat is often associated with success and social status. People are only likely to reject meat once they have the opportunity to consume as much as they want.

Gender is another patterned feature of vegetarians in North America. Studies have consistently found that about 70 percent of all vegetarians are female. Several explanations are possible. First, the foods embraced by vegetarian diets are those already symbolically linked with feminine attributes, that is, foods that are light, low-fat, and not bloody (as people often equate blood with strength). For many people meat and masculinity are inextricably linked; therefore it is easier for women than for men to escape cultural expectations. In addition, women tend to be more concerned with weight loss, and many pursue a vegetarian diet as the means to that end. Finally, some researchers hold that women are more likely than men to hold a compassionate attitude toward animals, leading them to have more concern about killing animals for food. All of these factors contribute to the reality that women are more likely than men to become vegetarians.

Studies have suggested that vegetarians may share a variety of other characteristics as well. For example, while vegetarians are less likely than the general population to follow a conventional religion, they are more likely to describe themselves as spiritual and to practice some form of yoga or meditation. They are more likely to describe themselves as “liberal” and less likely to adhere to traditional values that embrace upholding the existing social order. They are also less likely than the general population to smoke cigarettes and drink alcohol. Yet it is important to point out that vegetarians are more different than similar in their social backgrounds, political beliefs, and health practices.

### Reasons for Vegetarianism

People become vegetarians for a variety of reasons, including personal health, a concern for the treatment of farm animals and the environment, spiritual beliefs, and sometimes simply a physical disgust toward meat. Most commonly North Americans follow a gradual path toward vegetarianism that starts with a health motivation. They perceive that a vegetarian diet will give them more energy, will help them lose weight, or will assuage a health condition, such as heart disease or cancer. Other people become vegetarians out of a concern for the rights of animals or a belief that meat production causes devastating effects to the environment. Some grew up with or adopted a religion (for example, Hinduism, Jainism, Seventh Day Adventism) that encourages or requires a vegetarian diet. Still others are concerned with world hunger and take the view that many more people can be fed on a vegetarian diet than on a meat-based one.

People tend to first stop eating the foods they view as the most offensive or unhealthy. For most gradual vegetarians this is red meat. The typical path for a new vegetarian is to stop eating red meat first, then poultry, and then fish. Some move to further prohibitions by adopting a vegan lifestyle as they eliminate eggs, dairy products, and other animal by-products. As people progress along the vegetarian “path,” they tend to adopt new rea-

sons to support their lifestyle practices. Most commonly people begin with a health motivation and gradually become concerned with the humane treatment of animals and protecting the environment, and many develop a disgust response to meat products.

### Scientific Controversy and Gradual Acceptance

After the mid-1800s, the medical establishment responded to advocates’ claims that vegetarian diets are healthful and desirable. In the 1800s vegetarians were primarily labeled as “quacks” and were characterized in the popular press as weak, sallow, and emaciated. The notion that vegetarians are weak and lack energy persisted throughout the twentieth century.

In the 1970s dietitians and nutritional scientists focused much attention on vegetarian diets, and many considered them a medical problem. These nutritionists were particularly concerned that vegetarians did not consume adequate protein. During the 1970s and 1980s many articles in nutrition journals debated whether or not vegetarian diets were desirable and gave advice about how to deal with obstinate vegetarian clients. Over time, however, dietitians accepted the idea that vegetable protein derived primarily from grains and legumes is not of lesser quality than protein from meat and other animal-based foods. Eventually dietitians accepted their clients’ vegetarian lifestyles and began to help them improve those diets instead of trying to convert them to meat eating.

By the early twenty-first century the American Dietetic Association and the U.S. Department of Agriculture both endorsed the healthfulness of vegetarian diets when they are appropriately planned (just as any diet should be). However, new controversies have arisen, particularly regarding the necessity and desirability of consuming milk and other dairy products. This controversy was spurred in the late 1990s in large part by the view of the renowned pediatrician Benjamin Spock that children should be fed a vegan diet after age two. This stance has generated much debate, as it challenges the deep-seated cultural notion that milk is necessary to build strong bones and to foster physical development.

### The Vegetarian Movement

Most people adopt vegetarian diets at least in part as a result of interactions with other practicing vegetarians. People rarely become vegetarians in isolation. Through social interactions, people learn the reasons for adopting vegetarian diets and how to successfully follow them. For example, they learn how to cook vegetarian meals and where to buy foods that will ensure that their new diets are both nutritionally sound and personally satisfying. Consequently, vegetarianism is typically much more of a social experience than an individual experience.

Numerous vegetarian organizations facilitate this social learning. Although they are largely distinct from animal rights and environmental organizations, they sometimes share leadership and other resources. At the

national level the American Vegan Society, the North American Vegetarian Society, and EarthSave hold conferences, distribute literature on vegetarian diets, and help form local vegetarian societies. In these local groups people interact, share potluck meals, listen to speakers, and sometimes distribute vegetarian literature to the public at local events.

Other national vegetarian organizations, such as FARM, Vegan Action, and Vegan Outreach, encourage vegetarians to take a more activist stance. The Vegetarian Resource Group distributes well-documented, scientifically oriented literature to the public and works with governmental and professional organizations to advance the movement's goals. All of these groups primarily promote vegetarianism through education and embrace the varied reasons for adopting vegetarian diets.

**VITAMIN C.** Vitamin C is also known as ascorbic acid, because it is the "anti-scorbutus" vitamin (*scorbutus* being the Latin name for the disease of scurvy). Unlike other vitamins, it is only required by a few species, particularly humans, but also guinea pigs and bats. Others, such as dogs and cats, make it for themselves by oxidiz-

ing glucose. Species that require the vitamin have lost the key enzyme that manufactures vitamin C because of a genetic mutation during evolution, in a period when the natural diet was vitamin C-rich, resulting in no disadvantage. The empirical formula of the vitamin is  $C_6H_8O_6$ ; it is a white crystalline powder, freely soluble in water and pleasant tasting, but easily destroyed by heat and oxidation. A daily intake of as little as 7 milligrams (mg) has been found to be sufficient to prevent the development of signs of scurvy, but the usual recommendation is that adults should aim to take some 70 mg per day, partly as a safety factor. One school of thought recommends much higher intakes, of perhaps 1,000 mg, on the grounds that its antioxidant properties will increase resistance to infections, aging, and cancer. This assertion remains controversial, however. The Institute of Medicine recommends 2,000 mg/day as the tolerable upper intake level for adults. High levels may have a laxative effect, but this is welcomed by many people. The main natural sources of the vitamin are fresh fruits and vegetables. One of the first fruits valued for its antiscorbutic activity was the orange—each one containing some 50 to 75 mg of the vitamin. In contrast, an apple of similar size has only 7 mg. Potatoes have been an important source of the vitamin in some cultures, not because they are particularly rich, but because they have been consumed in large amounts.

The value of potatoes as a source of vitamin C is influenced by the way in which they are prepared. Thus, one large potato cooked in its skin in a microwave oven may supply 30 mg of the vitamin, but the same quantity may supply only a third of that or even less when boiled, mashed, and reheated on a buffet table. One problem has been to understand how Eskimos, in their traditional lifestyle, managed to obtain enough vitamin C when they had no access to fruits or vegetables. Although fully cooked meats have lost essentially all their vitamin C, the scarcity of fuel meant that the Eskimos could only bring a piece of meat just to the boil in water. They then drank the vitamin-rich broth and ate the meat, thus meeting their need for vitamin C. Liver cooked in this way is richer than muscle meats in vitamin C. Cows' milk too loses most of its vitamin C when heat-sterilized or "condensed," and infantile scurvy has been a problem where mothers have economized by using canned milk as a complete food for their infant.

## VITAMINS.

### OVERVIEW

The word “vitamin” came from the term *vita mines* (vital amines), which was introduced by Casimir Funk, who, in 1912, isolated a growth factor from rice polishings that contained an amine (a compound incorporating a nitrogen atom with two hydrogen atoms) and could cure the disease beriberi. Several other growth factors were identified early in the twentieth century as well, and these substances were also called vitamins even though they did not contain an amine. Vitamins are classified into two major groups: fat-soluble and water-soluble. (See the Appendix for a complete chart of vitamins.)

### Fat-Soluble Vitamins

**Vitamin A.** In the early 1900s, Sir Frederick Hopkins demonstrated that animals would not grow if lard was provided as a sole dietary lipid. When a small quantity of milk containing fat was added to the diet, the animals thrived. The fat-soluble factor was isolated and designated as vitamin A, later called retinol or retinal; these and similar compounds are referred to as retinoids. Carotenoids, which are essentially two retinoids joined tail to tail, are inactive forms of vitamin A and are called provitamin A. They are converted to vitamin A in the intestine and liver. Vitamin A and carotenoids are absorbed in the chylomicron (a lipoprotein particle that transports lipids from the intestine) fraction and stored in the liver. Some foods such as milk are fortified with vitamin A. Rich sources of carotenoids include carrots, leafy green vegetables, and pink grapefruit.

Vitamin A is, chemically, a subgroup of retinoids, which are defined as a class of compounds that consist of a six-membered ring and a side chain with four conjugated double bonds (four isoprenoid units). The term vitamin A is used to describe retinoids exhibiting qualitatively the biologic activity of the retinoid, retinol.

Vitamin A binds to a retinol-binding protein that transports the light-sensitive vitamin to various target tissues, including the eyes, skin, and gastrointestinal track. The major functions of vitamin A include vision and regulation of cellular proliferation and differentiation. Vitamin A functions on vision by interacting with the rod and cone cells in the retina. It is responsible for absorbing light. The 11-*cis* form of vitamin A (retinal) combines with the protein opsin to form rhodopsin in the rod cells and iodopsins in the cone cells. The rhodopsin and iodopsins absorb light at various wavelengths and trigger a nerve impulse to the visual cortex in the brain that is ultimately perceived as black-and-white and color vision, respectively.

Vitamin A's other major physiologic function is to maintain the health of skin and mucous-secreting cells by regulating their cellular activity and maturation. The dietary requirements depend on age.

The major consequence of vitamin A deficiency, which continues to be a serious nutritional problem among millions of schoolchildren in southern and southeastern Asia and parts of Africa and South America, is night blindness. Vitamin A deficiency can lead to complete blindness and severe damage to the outer covering of the eye (the cornea), often causing it to perforate, with loss of the fluid from inside the eye (keratomalacia). Vitamin A deficiency also produces changes in the skin that are related to the inability of the skin cells to mature and produce keratin properly. This leads to follicular hyperkeratosis and phrynodema (a condition characterized by rough, dry skin). Vitamin A deficiency has also been linked to increased mortality in early childhood.

Acute and chronic ingestion of excessive amounts of vitamin A can cause a multitude of symptoms and consequences. The most serious is that it can cause severe birth defects, spontaneous abortions and learning defects, and skin and epithelial-cell exfoliation. Inexperienced white explorers of the Arctic who ate polar-bear liver in excess developed severe vitamin A intoxication that caused a total sloughing of their skin and mucous-secreting cells in the upper airway and esophagus, bringing on painful death. (This is in contrast to the indigenous Inuit, who specifically avoid eating polar-bear liver.)

**Vitamin D.** One of the consequences of the industrial revolution was the high incidence of the bone-deforming disease rickets. It was estimated, at the turn of the twentieth century, that more than ninety percent of children living in the industrialized cities of northern Europe and the northeastern United States had rickets. It had been known that cod-liver oil possessed a factor that had antirachitic activity. Originally, it was thought that the antirachitic factor was vitamin A. However, Hopkins heated cod-liver oil to destroy the vitamin A activity and demonstrated that it still possessed antirachitic activity. This new fat-soluble vitamin was labeled vitamin D. It was also recognized that exposure of food, animals, and humans to ultraviolet radiation also prevented and cured rickets.

There are two principal forms of vitamin D: Vitamin D<sub>2</sub> comes from the precursor ergosterol found in yeast and plants, and vitamin D<sub>3</sub> comes from the cholesterol precursor 7-dehydrocholesterol that is found in the skin of reptiles, birds, mammals, and humans. Vitamin D<sub>2</sub> and vitamin D<sub>3</sub> are essentially equally active in most birds and in most mammals, including humans. Chickens and New World monkeys, however, cannot utilize vitamin D<sub>2</sub>. There are very few foods that naturally contain vitamin D. Fatty fish, such as salmon and mackerel, and fish-liver oils, such as cod-liver oil are good sources of vitamin D. Cow's milk and human milk have very little vitamin D. However, in the United States and Canada, milk and some breads and cereals are fortified with vitamin D. In Europe, fortification of foods with vitamin D was outlawed when sporadic cases of vitamin D intoxication were observed in children in the 1950s. Today

some margarine and cereals are fortified with vitamin D in Europe, but milk is not.

Vitamin D<sub>3</sub> is made by the action of sunlight on the skin. Provitamin D<sub>3</sub> (7-Dehydrocholesterol) absorbs solar ultraviolet B radiation (wavelengths 290–315 nm) and is transformed into previtamin D<sub>3</sub>. Previtamin D<sub>3</sub> is unstable at body temperature and isomerizes (rotates its double bonds) to vitamin D<sub>3</sub>. Once formed, vitamin D<sub>3</sub> leaves the skin and enters the circulation, bound to the vitamin D binding protein. It travels to the liver where it is activated to 25-hydroxyvitamin D [25(OH)D]. This form, however, is biologically inert at physiologic concentrations and is the major circulating form of vitamin D. It is, nevertheless, the form that is measured to determine the vitamin D status of an individual, because it represents a summation of dietary and skin sources of vitamin D. 25(OH)D is transported on the vitamin D binding protein to the kidney, where it undergoes its final activation on carbon 1 to form 1,25-dihydroxyvitamin D [1,25(OH)<sub>2</sub>D], the biologically active form of vitamin D.

The principal function of vitamin D is to maintain blood calcium and phosphorus in the normal range in order to promote neuromuscular function and to maintain metabolic activities. It accomplishes this by enhancing the efficiency of intestinal calcium transport in the small intestine and by stimulating precursor cells of osteoclasts to become mature osteoclasts. Among the functions of osteoclasts is to remove calcium from bone. Serum calcium and phosphorus are in the form of Ca<sub>x</sub>(PO<sub>4</sub>). When these compounds are in the normal range, they are in a supersaturated state that can thus be deposited in the skeletal matrix as calcium hydroxyapatite.

1,25(OH)<sub>2</sub>D interacts with a receptor in the nucleus of cells, known as the VDR (vitamin D receptor). It also complexes with the “retinoic acid x” receptor in that cellular structure. These receptor-activated vitamin D complexes find their way to genes that have responsive elements known as the vitamin D-responsive element. These elements in turn unlock genetic information that is responsible for various biologic functions in intestine and bone. It is recognized that a wide variety of tissues including the brain, parathyroid glands, breast, prostate, stomach, and skin also have VDR. Although the exact physiologic function of 1,25(OH)<sub>2</sub>D in these non-calcium-regulating tissues is not well understood, 1,25(OH)<sub>2</sub>D inhibits cellular proliferation and induces terminal differentiation of a wide variety of cells, including bone, skin, skeletal muscle, breast, and prostate. The dietary requirement depends on age.

Vitamin D deficiency results in a decrease in the efficiency of intestinal calcium absorption that in turn leads to a decrease in unbound or free calcium concentrations in the circulation. This is recognized by the parathyroid gland and results in an increase in the production and secretion of parathyroid hormone (PTH). PTH enhances calcium reabsorption by the kidney and causes increased output of phosphate in the urine. PTH also stimulates

the kidney to produce more 1,25(OH)<sub>2</sub>D. The net effect of vitamin D deficiency is a low-normal serum calcium and a low serum phosphorus (due to the PTH-induced phosphate wasting in the kidney). Thus calcium and phosphorus concentrations fall below supersaturating levels, thereby resulting in poorly mineralized bone. In children, this causes rickets and, in adults, osteomalacia. In addition, vitamin D deficiency in adults can precipitate and exacerbate osteoporosis. In winter, little if any vitamin D can be made in the skin of people who live above 40° north or below 40° south of the equator. An increase in the zenith angle of the sun due to latitude, time of day, and season of the year will dramatically reduce the production of vitamin D<sub>3</sub> in the skin. Moreover, aging and sunscreen use can markedly reduce the production of vitamin D by more than 60 percent and 99 percent, respectively. Rickets due to vitamin D deficiency in children may include bowlegs or knock-knees, widening of the ends of the long bones, growth retardation, and muscle weakness. In adults, in addition to osteomalacia and increased risk of osteoporosis, it causes bone pain, muscle weakness, and fractures.

The safe upper limit for Vitamin D is 2,000 units a day. Although it is difficult to ingest enough to cause vitamin D intoxication, it can occur. Usually, oral ingestion of 10,000 units a day and greater will cause vitamin D intoxication. This intoxication causes an elevation in the blood levels of calcium and phosphorus, which results in the calcification of soft tissues, including the kidney and major blood vessels, and may also cause the formation of kidney stones.

**Vitamin E.** The discovery of vitamin E (tocopherols—from *toc-* meaning ‘childbirth’, *phero-* meaning ‘bringing forth’, and *-ol* representing the alcohol portion of the molecule) was due to the observation that supplementation of the diet with vitamin E prevented fetal death in animals that were fed a diet containing rancid lard. There are eight naturally occurring vitamin E compounds. Four of them are known as tocopherols and four are known as tocotrienols. The most abundant form of vitamin E is alpha-tocopherol. One of the major functions of vitamin E is to act as a biologic antioxidant to protect the sensitive cellular membranes from oxidative destruction. The major sources of vitamin E consumed by Americans are vegetables and seed oils, such as corn oil, soybean oil, and safflower oil. Wheat germ is a rich source of vitamin E. Although butter contains very little vitamin E, American margarine contains a significant amount of this antioxidant vitamin.

Vitamin E, like the other fat-soluble vitamins, is absorbed in the chylomicron fraction into the lymphatic system and is transported into the venous blood. The dietary requirements depend on age.

There have been difficulties in defining a clinical syndrome that correlates with vitamin E deficiency in humans. Vitamin E deficiency is associated with anemia in newborns.

Toxicity from excess vitamin E has been associated with increased bleeding tendency in adults and impaired immune function, decreased levels of vitamin K-dependent clotting factors, and impairment of leukocyte function.

**Vitamin K.** Vitamin K was discovered by Henrik Dam in Copenhagen in 1929. He observed that chicks fed a fat-free diet developed severe bleeding under the skin and in the muscle and other tissues. He named this new fat-soluble vitamin, vitamin K (for "Koagulation vitamin"). Vitamin K is distributed widely in both animal and vegetable foods as well as in milk. It comes in several forms: vitamin K<sub>1</sub> comes from plants and is known as phyloquinone, and vitamin K<sub>2</sub>, first isolated from fish meal and in animal foods, comprises a group of compounds known as menaquinones. In addition, bacterial flora in the intestine synthesize menaquinones that are bioavailable.

Vitamin K, like other fat-soluble vitamins, is absorbed in the chylomicron fraction and then appears in the lymph and subsequently in the venous circulation. The major physiologic function of vitamin K is to activate blood-clotting proteins. This is accomplished by the modification of a substance, glutamate, found in several precoagulant factors, including factors II, VII, VIII, and X, that are produced in the liver. Vitamin K is also responsible for the modification of other proteins, including the major noncollagenous protein in bone. The dietary requirements depend on age.

Vitamin K deficiency is rare because of the widespread distribution of the vitamin in plant and animal foods and because microbiotic flora in the normal gut synthesize menaquinones. However, vitamin K deficiency in breast-fed newborns remains a major worldwide cause of infant morbidity and mortality. Infants have very little stored vitamin K at birth, and the gut is nearly sterile during the first few days of life. As a result, infants can develop a severe bleeding condition known as hemorrhagic disease of the newborn if they do not obtain vitamin K during the first few days of life from an exogenous source, particularly since mother's milk contains little vitamin K and few bacteria other than those it picks up from maternal skin as an infant suckles. Adults who have intestinal malabsorption syndrome and who are taking antibiotics can become severely vitamin K-deficient. This can lead to generalized bleeding from all orifices.

There are no reported cases of intoxication due to excessive ingestion of phyloquinone. Ingestion of excessive amounts of menadione, a vitamin K precursor, can cause anemia secondary to the destruction of red blood cells, and an alteration in bilirubin metabolism causing hyperbilirubinemia in infants (kernicterus).

## Water-Soluble Vitamins

**Thiamine (vitamin B<sub>1</sub>).** Beriberi is a disease with a constellation of systems affecting the nervous and cardiovascular systems. It was first described by the Chinese

in 2697 B.C.E. In 1926, B. C. P. Jansen and W. F. Donath identified a factor from rice-bran extracts that prevented beriberi. The antiberiberi factor was identified chemically and called thiamine (vitamin B<sub>1</sub>). Thiamine is found in yeast, lean pork, and legumes. It serves as a receptor for high-energy pyrophosphate. It is this form of the vitamin that provides its chemical function. Pyrophosphate is extremely important for the generation of energy in the cell. However, it cannot enter the cell unless it is attached to thiamine. Thiamine is absorbed by the small intestine and transported to the liver. The major biochemical function of thiamine is to act as a coenzyme (that is, to provide a transfer site) in the alpha-keto acid carboxylation pathway. The dietary requirements depend on age.

Thiamine deficiency causes beriberi. Anorexia, neuritis, gastrointestinal dysfunction, cardiac irregularities, and muscle atrophy are present. There are three types of this disorder: wet, dry, and infantile. Wet beriberi is associated with body fluid retention (edema). Dry beriberi is related to neurologic abnormalities. It is recognized that alcoholics who have poor nutrition and thiamine deficiency, when receiving intravenous fluids, for example in the emergency room of a hospital, can develop severe altered mental states known Wernicke's and Korsakoff's syndromes. Wet beriberi is associated with heart abnormalities; dry beriberi is associated with neurological abnormalities that can cause permanent confusion if not treated in a timely manner.

Excessive ingestion of thiamine is cleared by the kidneys. There is no evidence that ingesting excessive amounts causes toxicity.

**Riboflavin.** In the 1920s, another water-soluble vitamin was discovered; it exhibited antipellagra activity and was termed vitamin B<sub>2</sub>. The substance was found to be yellow in color and was identified as a coenzyme, riboflavin 5'-phosphate (flavin mononucleotide or FMN).

The more abundant form of this vitamin is a complex flavin-adenine dinucleotide (FAD) that also participates as a coenzyme. Usually, the FMN and FAD are associated loosely with proteins and are released in the acidic gastrointestinal juices. The vitamin is absorbed by the proximal small intestine. Sources of riboflavin include eggs, lean meats, milk, broccoli, and enriched breads and cereals.

The physiologic function of riboflavin is to participate in oxidation-reduction reactions in numerous metabolic pathways and in energy production via the respiratory chain in the mitochondria. The dietary requirements depend on age.

Riboflavin is distributed widely in foodstuffs, and therefore deficiency is not common. However, there are reported cases of deficiency that are characterized by sore throat, hyperemia and edema of the pharyngeal and oral mucosal membranes, cheilosis (abnormal scaling and fissuring of the lips), angular stomatitis (surface inflamma-

tion of the mouth), glossitis (inflammation of the tongue), seborrheic dermatitis (an inflammation of the skin involving oversecretion by the oil-producing cutaneous glands), and anemia. Severe riboflavin deficiency can affect the conversion of vitamin B<sub>6</sub> to its coenzyme and reduce the conversion of tryptophan, an amino acid found in proteins of animal and plant origin, to niacin (see next section). Deficiency is principally due to abnormal digestion, abnormal absorption, or both. People who are lactose-intolerant—a condition that is most common among blacks and Asians—often limit consumption of milk (as noted above, an excellent source of riboflavin); they may therefore be at increased risk for riboflavin deficiency. Intestinal malabsorption syndromes, including tropical sprue celiac disease, small bowel resection, and gastrointestinal and biliary obstruction can lead to riboflavin deficiency.

There is no evidence that toxicity can occur as a result of excessive ingestion of riboflavin. The most likely reason for this is that riboflavin is cleared rapidly by the kidney and is not stored in the body.

**Niacin.** In the mid-1700s, a Spanish physician, Gaspar Casal, recognized a disease known as pellagra that caused diarrhea, dementia, and dermatitis in maize-eating (corn-eating) populations throughout the world. In 1937, Conrad Elvehjem and his colleagues observed that nicotinic acid was an effective treatment for pellagra. Nicotinic acid is synonymous with both niacin and nicotinamide. It is associated with ribose lyphosphate to form nicotinamide adenine dinucleotide (NAD) and NAD phosphate. Most niacin in food is present as a component of NAD or NADP and is relatively stable to cooking and storage. Good sources of niacin include meats (especially liver), fish, legumes such as peanuts, some nuts, and some cereals. Both coffee and tea also contain reasonable amounts of this vitamin. Niacin is unique among the B vitamins because its precursor amino acid, tryptophan, can help meet the daily niacin requirement.

Niacin has a multitude of physiologic functions in a wide variety of metabolic pathways that are related to energy production and biosynthetic processes. At least two hundred enzymes are dependent on NAD and NADP. Both of these substances act as electron acceptors or hydrogen donors. Most NAD-dependent enzymes are involved in catabolic reactions, whereas NADP is used more commonly for reductive biosyntheses of fatty acids and steroids, for example. The dietary requirements depend on age.

Niacin deficiency causes pellagra. This condition is associated with diarrhea, dementia, and dermatitis. It is endemic in India and in parts of China and Africa. The classic appearance of pellagra is a pigmented rash that develops symmetrically in areas of the skin exposed to sunlight. The tongue can become bright red and there is often vomiting and diarrhea. Patients can also exhibit

anxiety or sleeplessness, and can become disoriented and delusional.

Nicotinic acid is now used to treat hypercholesterolemia. Side effects of large amounts of nicotinic acid include flushing of the skin, abnormalities in liver function, and hyperglycemia. At extremely high ingestion levels, nicotinamide causes death in rats.

**Pyridoxine (vitamin B<sub>6</sub>).** Vitamin B<sub>6</sub> was identified in the 1930s. Like many of the water-soluble B vitamins, vitamin B<sub>6</sub> includes a group of compounds that act as a coenzyme phosphate donor. These include pyridoxal 5'-phosphate (PLP), and pyridoxamine 5'-phosphate (PMP). Plants foods contain predominantly pyridoxine, whereas animal products contain primarily pyridoxal and pyridoxamine. Vitamin B<sub>6</sub> is absorbed mainly by the lower small intestine (jejunum).

Like many of the other coenzyme B vitamins, vitamin B<sub>6</sub> has numerous biologic functions that are related to metabolism. B<sub>6</sub> is critically important for the production of glucose. PLP is also necessary for the conversion of tryptophan to niacin, which is why the two are often associated. The dietary requirements depend on age.

As with many of the other B vitamins, there are a wide variety of clinical symptoms associated with vitamin B<sub>6</sub> deficiency including an abnormal electroencephalogram, convulsions, stomatitis, cheilosis, glossitis, irritability, depression, and confusion.

High doses of pyridoxine have been used to treat premenstrual syndrome and other neurological diseases. Such uses have resulted in neurotoxicity and photosensitivity.

**Pantothenic acid.** Pantothenic acid was one of the more difficult vitamins to isolate and separate from the other water-soluble B vitamins. Finally in the 1940s, it was synthesized and was found to be associated with coenzyme A (CoA). CoA is an essential cofactor for biologic acetylation reactions and participates in the respiratory tricarboxylic acid cycle, fatty-acid synthesis and degradation, and a wide variety of other metabolic and regulatory processes. The dietary requirements depend on age.

Pantothenic acid deficiency affects the adrenal gland, nervous system, skin, and hair adversely. Pantothenic acid deficiency in humans is rare, but has been associated with fatigue and depression.

High doses of calcium pantothenate have not been found to be toxic in humans.

**Folic acid and cobalamin (vitamin B<sub>12</sub>).** In the mid-1800s, several physicians recognized that a severe form of anemia was associated with disorders of the digestive system. In 1934, William Castle and his associates observed that normal human gastric juice contained an intrinsic factor (IF) that combines with an extrinsic factor in animal-protein food, resulting in the absorption of a vitamin that

prevents anemia. Vitamin B<sub>12</sub> was isolated in 1948 and was shown to be the extrinsic antianemia factor.

Vitamin B<sub>12</sub> absorption is unique among the B vitamins, in requiring an IF to help its absorption. Folate, on the other hand, is absorbed directly by the upper (proximal) small intestine.

Whereas vitamin B<sub>12</sub> is found only in animal protein, folates are common in nature and present in nearly all natural foods. The dietary requirements depend on age.

Vitamin B<sub>12</sub> deficiency can occur either because of inadequate vitamin B<sub>12</sub> ingestion or because of the loss or inadequacy of production of intrinsic factor in the stomach. The two most notable clinical signs of vitamin B<sub>12</sub> deficiency include megaloblastic anemia and neurological deficits. Vitamin B<sub>12</sub> deficiency can cause paresthesia (especially numbness and tingling in the hands and feet); the diminution of vibration and position sense; unsteadiness; poor muscular coordination with ataxia (loss of muscular coordination); moodiness; mental slowness; poor memory; confusion; agitation; depression; and central visual loss. Delusions, overt psychosis, and paranoid ideas may occur in severe deficiency.

Folate deficiency also causes megaloblastic anemia and can cause neurological abnormalities as well, including irritability, forgetfulness, and hostile and paranoid behavior. For adults, ingestion of ten thousand times the minimum requirement for B<sub>12</sub> and several hundred times that for folic acid has not been associated with toxicity.

**Biotin.** Biotin was identified in the 1940s. It, like many of the other B vitamins, acts as a coenzyme. Biotin is plentiful in foods such as liver, egg yolk, soybeans, yeast, cereals, legumes, and nuts. With the exception of cauliflower and mushrooms, vegetables, fruits, and meats, however, are poor sources of biotin. Biotin is also present in human and cow's milk. The major physiologic functions of biotin are related to carbohydrate and lipid metabolism. The dietary requirements depend on age.

Biotin deficiency causes mental-status changes, myalgia (muscle pain), hyperesthesia (abnormal sensitivity to pain, touch, cold, etc.), localized paresthesia, and anorexia with nausea. Dermatitis can also be associated with deficiency. The immune system is impaired in biotin-deficient animals. Neurological disorders including seizures and developmental delays have been reported in children. There have been no reports of intoxication due to excessive biotin ingestion.

**Vitamin C.** Scurvy is recognized as a deficiency disease that has taken a high toll in human suffering and death. The disease, which is caused by vitamin C deficiency, was recognized in ancient times by the Egyptians, Greeks, and Romans. It was especially prevalent among sea explorers of the sixteenth to eighteenth centuries. Typically, sailors developed bleeding and rotting gums, swollen and inflamed joints, dark blotches on the skin,

and muscle weakness that occurred within months when at sea. It was the loss of 1,051 sailors in 1774 that prompted the British Admiralty to seek a cure for this devastating disease. They found that lemon or lime juice could prevent the disease. In the late 1920s, Albert Szent-Györgyi and Glenn King isolated vitamin C and identified it as hexuronic acid. Vitamin C is water-soluble and is absorbed efficiently by the small intestine. Its major physiologic function is to provide reducing activity for a wide variety of metabolic steps. It is important for the modification of lysine and proline—two amino acids that are common components of collagen. These modifications result in the cross-linking of collagen strands providing structural support for this essential component of bone and fibrous tissues. The dietary requirements depend on age.

As noted, vitamin C deficiency causes scurvy, which is associated with a wide variety of abnormalities, including hemorrhages under the skin, black-and-blue marks, hyperkeratosis, joint discomfort, edema, weakness, fatigue, lassitude, depression, and hysteria.

It was suggested by the Nobel Prize Laureate Linus Pauling that extremely high doses of vitamin C could prevent cancer. With the exception of excessive amounts of vitamin C causing bowel impaction via a large number of vitamin C tablets ingested, there are very few serious consequences from an overingestion of vitamin C, though it can increase the risk of kidney stones and other renal diseases.

**Other nutrients.** Other nutrients that are essential could be considered vitamins. These include choline, carnitine, inositol, and taurine.

## VITAMINS.

### WATER-SOLUBLE AND FAT-SOLUBLE VITAMINS

Vitamins are among the nutrients found to be essential for life. Unlike other classes of nutrients, vitamins serve no structural function nor do they provide significant energy. Their various uses tend to be highly specific. Common food forms of most vitamins require some metabolic activation into a functional (active) form. Although vitamins share these general characteristics, they show few close chemical or functional similarities. For example, some vitamins function as coenzymes, others function as antioxidants, and two vitamins, A and D, function as hormones.

Fourteen substances are now generally recognized as vitamins. Vitamins are frequently described according to their solubility; they may be either fat-soluble or water-soluble. This method of classification dates back to the history of their discovery as labeled by McCollum as “fat-soluble A” and “water-soluble B.”

Other sections in this encyclopedia describe the chemistry, biochemistry, and physiology of the vitamins. This article provides additional information that is focused on dietary requirements, upper levels (to avoid toxicity from supplementation), and food sources. (See sidebar for definition of terms, and see Appendix for a complete chart of vitamins.)

### Water-Soluble Vitamins

**Thiamin.** Thiamin was the first vitamin to be identified. In modern times, thiamin deficiency is seen most commonly in association with chronic alcoholism. Only a small percentage of large doses are absorbed, and elevated serum levels result in its active urinary excretion. After an oral dose of the vitamin, peak excretion occurs in about two hours (Davis et al., 1984). Total body thiamin content in adults is approximately 30 milligrams with a half-life of 9 to 18 days (Ariaey-Nejad et al., 1970).

The recommended dietary allowance (RDA) for thiamin in adult women is 1.1 mg/day and in adult men it is 1.2 mg/day. The RDA for pregnancy and lactation is 1.4 mg/day (FNB, 1998). It should be noted that increased needs exist in persons being treated with hemodialysis or peritoneal dialysis, individuals with malabsorption syndrome, women carrying more than one fetus, and women nursing more than one infant.

There are no reports of adverse effects from the consumption of excess thiamin consumed in food or supplements. No upper level (UL) can be set due to the lack of reported findings associated with adverse effects. Supplements that contain up to 50 mg/day are available over-the-counter with no reported problems.

Food sources from which most of thiamin in the United States is derived include enriched, fortified, or whole-grain products, such as bread, bread products, mixed foods that contain grain, and ready-to-eat cereals. Foods that are especially rich in thiamin include yeast,

### DIETARY REFERENCE INTAKES

*See Appendix for full chart of Dietary Reference Intakes.*

**Recommended Dietary Allowance (RDA)**—the dietary intake level that is sufficient to meet the nutrient requirement of nearly all (97 to 98 percent) healthy individuals in a particular life stage and gender group.

**Adequate Intake (AI)**—a recommended intake value based on observed or experimentally determined approximations or estimates of nutrient intake by a group (or groups) of healthy people that are assumed to be adequate—used when an RDA cannot be determined.

**Tolerable Upper Intake Level (UL)**—the highest level of nutrient intake that is likely to pose no risk of adverse health effects for almost all individuals in the general population. As intake increases above the UL, the risk of adverse effects increases.

SOURCE: Food and Nutrition Board, Institute of Medicine. *Dietary Reference Intakes* (FNB, 2000, p. 3).

lean pork, and legumes. Thiamin is absent from fats, oils, and refined sugars. Milk, milk products, seafood, fruits, and vegetables are not good sources.

**Riboflavin.** The second vitamin discovered was named vitamin B<sub>2</sub> or riboflavin. Most dietary riboflavin is consumed as a complex of food protein. Signs of riboflavin deficiency are sore throat, redness, and edema of the throat and oral mucous membranes, cheilosis (cracking of the skin around the mouth), and glossitis (red tongue). Vitamin B<sub>2</sub> deficiency most often occurs in combination with other nutrient deficiencies. The B vitamins are quite interrelated; for example, niacin requires riboflavin for its formation from the amino acid tryptophan, and vitamin B<sub>6</sub> requires riboflavin for conversion to the active coenzyme form (McCormick, 1989).

The RDA for riboflavin has been set at 1.3 mg/day for men and 1.1 mg/day for women through age seventy years and older. For pregnancy, the RDA for riboflavin is set at 1.4 mg/day and it is 1.6 mg/day for lactation (FNB, 1998).

When riboflavin is absorbed in excess, very little is stored in the body tissues. Excess is excreted via the urine, and the amount varies with intake, metabolic events, and age (McCormick and Greene, 1994). No adverse effects associated with riboflavin consumption from food or supplements have been reported. No adverse effects were reported from a single dose of up to 60 milligrams and 11.6 milligrams of riboflavin given as a single intravenous (IV) dose (Zempleni et al., 1996).

The greatest contribution of riboflavin from the diet comes from milk and milk drinks, followed by bread products and fortified cereals. Especially good food sources of riboflavin are eggs, lean meats, milk, broccoli, and enriched breads and cereals. Recall that riboflavin loss occurs when it is exposed to light, so store milk in opaque containers or away from the light.

**Niacin.** The term “niacin” refers to nicotinamide and nicotinic acid. The coenzymes, the active form of niacin in the body, are synthesized in all tissues of the body. The amount of niacin in the body is the result of absorbed nicotinic acid and nicotinamide, as well as conversion of the amino acid tryptophan (60 milligrams of tryptophan = 1 milligram of niacin; Horwitt et al., 1981). Excess niacin is excreted through the urine.

Pellagra is the classical manifestation of niacin deficiency. Pellagra has been seen in areas where corn (low in niacin and tryptophan) is the dietary staple. Enrichment and fortification of grain has virtually eliminated pellagra from the United States and Europe.

The RDA for adult men is 16 mg/day of niacin equivalents, and the RDA for women aged nineteen to over seventy is 14 mg/day. In pregnant women the RDA is 18 mg/day of niacin equivalents and in lactating women it is 17 mg/day (FNB, 1998).

Niacin, given as nicotinic acid in doses from 4 to 6 g/day, is one of the oldest drugs used in the treatment of hyperlipidemia, which consists of elevated blood levels of triglycerides and cholesterol. Niacin lowers low-density lipoprotein (LDL) cholesterol and triglyceride concentration. This therapeutic effect is not seen with nicotinamide. Nicotinic acid in therapeutic doses can cause flushing and headache in some people. These side effects are not harmful.

An upper limit for niacin was set at 35 mg/day for adults, if the niacin is obtained from supplements, not foods. Individuals who take over-the-counter niacin to “self-medicate” may exceed the UL on a chronic basis. The UL is not intended to apply to those receiving niacin under medical supervision.

Dietary intake of niacin comes mainly from mixed dishes containing meat, poultry, or fish, followed by enriched and whole-grain breads, and fortified cereals. Significant amounts of niacin are found in red meat, liver, legumes, milk, eggs, alfalfa, cereal grains, yeast, and fish.

**Vitamin B<sub>6</sub>.** Vitamin B<sub>6</sub> is a coenzyme for more than 100 enzymes involved in the metabolism of amino acids, glycogen, and nerve tissues (FNB, 1998). Microcytic anemia, reflecting decreased hemoglobin synthesis, can be seen in deficiency states. The interaction of vitamin B<sub>6</sub> and folate (another B vitamin discussed below) has been shown to reduce the plasma concentrations of homocysteine and decrease the incidence of cardiovascular disease (CVD) risk (Rimm et al., 1998). Subjects with the highest intake of folate and vitamin B<sub>6</sub> had a twofold reduc-

tion in CVD as compared to the group with the lowest intake.

In the 1970s there was quite a bit of discussion about the status of vitamin B<sub>6</sub> in women using oral contraceptives. This was probably an artifact of hormonal stimulation of tryptophan catabolism rather than vitamin B<sub>6</sub> deficiency. At the time these studies were conducted, estrogen concentrations were three to five times higher in contraceptive agents than they are today.

The RDA for vitamin B<sub>6</sub> is 1.3 mg/day for adult men and women up to age fifty years. The RDA for people over fifty years of age is 1.7 mg/day for men and 1.5 mg/day for women. For pregnant women the RDA is set at 1.9 mg/day and for lactating women, 2.0 mg/day (FNB, 1998).

No adverse effects have been associated with intakes of vitamin B<sub>6</sub> from food. However, large doses of pyridoxine used to treat carpal tunnel syndrome and premenstrual syndrome have been associated with sensory neuropathy (Schaumburg and Berger, 1988). These findings were noted with dosages from 2 to 6 g/day. It appears that the risk of developing sensory neuropathy decreases quite rapidly at dosages below 1 g/day. Thus, the UL for adults is set at 100 mg/day of vitamin B<sub>6</sub> as pyridoxine.

Food sources of vitamin B<sub>6</sub> include fortified, ready-to-eat cereals; mixed foods with meat, fish, or poultry as the main ingredient: white potatoes, starchy vegetables, and noncitrus fruits. Vitamin B<sub>6</sub> is widely distributed in foods; good sources are meats, whole-grain products, vegetables, and nuts.

**Folate.** Folate is a B vitamin that exists in many chemical forms (Wagner, 1996). Folic acid, the most stable form of folate, occurs rarely in food, but is the form used in supplements and fortified food products. Folate coenzymes are involved in numerous reactions that involve DNA synthesis, purine synthesis, and amino acid metabolism. The most well known is the conversion of homocysteine to methionine. It is this reaction that reduces the concentration of homocysteine in the plasma, and may lower the risk of cardiovascular disease (Rasmussen et al., 1996).

The metabolic interrelationship between folate and vitamin B<sub>12</sub> may explain why a single deficiency of either vitamin leads to the same hematological changes. In either folate or vitamin B<sub>12</sub> deficiency, megaloblastic changes occur in the bone marrow and other replicating cells.

Pregnant women are at risk for developing folate deficiency because of the heightened demands imposed by increased synthesis of DNA. Low folate status is associated with poor pregnancy outcome, low birth weight, and fetal growth retardation (Scholl and Johnson, 2000). Because of the possible incidence of neural tube defects (NTDs) during the preconception period (that is, just be-

fore and during the first 28 days of conception), the Food and Nutrition Board recommends that women who are capable of becoming pregnant should consume 400  $\mu\text{g}/\text{day}$  of synthetic folic acid, derived from dietary supplements or fortified food, in addition to their usual dietary intake (FNB, 1998). NTDs are the most common major congenital malformations of the central nervous system.

Recommendations for intake of folate are dependent on variation in bioavailability. Supplemental folate is nearly 100 percent absorbed, while absorption of folate found in foods is only about 50 percent. Fortified foods approach the level of bioavailability of folate found in supplements. This has led to the term Dietary Folate Equivalents or DFEs. Thus, dietary recommendations for folate intake are based on "folate equivalents." One  $\mu\text{g}$  of folate equivalents = 1  $\mu\text{g}$  of food folate = 0.5  $\mu\text{g}$  of folic acid taken on an empty stomach or = 0.6  $\mu\text{g}$  folic acid with meals. The RDA for women is 320  $\mu\text{g}$  dietary folate equivalents and for men it is 400  $\mu\text{g}$ . During pregnancy 600  $\mu\text{g}/\text{day}$  of folate is recommended and 500  $\mu\text{g}/\text{day}$  is recommended during lactation (FNB, 1998).

No adverse effects have been associated with the consumption of normal folate-fortified foods. However, the risk of neurological effects that result from vitamin B<sub>12</sub> deficiency that are masked with high doses of folate caused the FNB to set a UL. The UL for adults, nineteen years and older, is set at 1,000  $\mu\text{g}/\text{day}$  of folate from fortified food or supplements.

Folates are found in nearly all natural foods. Prolonged cooking or processing may destroy folate. Foods with the highest folate content include yeast, liver, other organ meats, fresh green vegetables, and some fruits (oranges, for example). Most of the dietary intake of folate in the United States comes from fortified ready-to-eat breakfast cereals followed by a variety of beans and peas, fresh and dried. As of 1 January 1998, all enriched cereal grains, pasta, flour, and rice are required to be fortified with folate at 1.4 mg/kg of grain.

**Vitamin B<sub>12</sub>.** Cyanocobalamin is the compound we call vitamin B<sub>12</sub>. This is the only vitamin B<sub>12</sub> preparation used in supplements. An adequate supply of vitamin B<sub>12</sub> is essential for normal blood formation and neurological function. The absorption of vitamin B<sub>12</sub> is dependent on several physiological steps. In the stomach, food-bound vitamin B<sub>12</sub> is dissociated from proteins in the presence of stomach acid. Vitamin B<sub>12</sub> then binds with protein and in the intestine the vitamin B<sub>12</sub> binds with intrinsic factor for absorption. If there is a lack of sufficient acid in the stomach or intrinsic factor in the intestine, malabsorption occurs and the resulting condition caused is pernicious anemia.

The anemia of vitamin B<sub>12</sub> deficiency (completely reversed by addition of B<sub>12</sub>) is indistinguishable from that seen with folate deficiency. Because up to 30 percent of people older than fifty are estimated to have atrophic gastritis with low stomach acid secretion, older adults may

have decreased absorption of B<sub>12</sub> from foods. Thus, it is recommended that most of the vitamin B<sub>12</sub> consumed by adults greater than fifty-one years of age be obtained from fortified foods or supplements.

The RDA of vitamin B<sub>12</sub> for men and women is 2.4  $\mu\text{g}/\text{day}$ , most of that amount coming from fortified foods or supplements in those over fifty years of age. During pregnancy, the RDA is 2.6  $\mu\text{g}/\text{day}$  and it is 2.8  $\mu\text{g}/\text{day}$  during lactation (FNB, 1998). No adverse effects have been associated with excess B<sub>12</sub> intake from food or supplements. After reviewing the literature, the FNB found insufficient evidence for determining a UL.

Vitamin B<sub>12</sub> is present in all forms of animal tissues. It is not present in plants and thus does not occur in fruits or vegetables. Because a generous intake of animal foods is customary in the United States, B<sub>12</sub> intake from foods is usually adequate. People who avoid eating animal products may obtain most of their requirement through fortified foods.

**Vitamin C.** Ascorbic acid (the chemical name for vitamin C) is a potent antioxidant in animals and plants. Vitamin C is important in the synthesis of collagen. Some evidence indicates that vitamin C reduces virus activity by inhibiting viral replication (Johnston, 2001). Many anecdotal reports support a role for vitamin C supplementation to reduce the severity of cold symptoms.

Some epidemiological evidence indicates that supplemental vitamin C protects against risk for myocardial infarction. However, large-scale epidemiological studies do not suggest a benefit of vitamin C supplementation on cardiovascular health risks (Kushi et al., 1996).

Non-heme iron absorption from food is enhanced two- to threefold in the presence of 25 to 75 mg of vitamin C, presumably because of the ascorbate-induced reduction of ferric iron to ferrous iron, which is less likely to form insoluble complexes in the intestine. However, vitamin C has no effect on increasing iron absorption from heme iron (Johnston, 2001). Unlike most animal species, humans lack the ability to synthesize ascorbic acid; thus, the diet is the sole source for this vitamin.

The current requirement of vitamin C is 90 mg/day for adult men and 75 mg/day for adult women. During pregnancy the RDA is 85 mg/day, and 120 mg/day during lactation. The UL for vitamin C was set at 2 g/day (FNB, 2000). This level was set as a guideline for people using dietary supplements and was based on reports of gastrointestinal symptoms reported when too much vitamin C was taken.

Almost 90 percent of vitamin C in the diet comes from fruits and vegetables, with citrus fruits, tomatoes, tomato juice, and potatoes being the major contributors. It is also added to some processed foods as an antioxidant.

**Pantothenic acid.** Pantothenic acid was named after the Greek, meaning "from everywhere," because it is so

widespread in foods. Pantothenic acid is essential in the diet because of the inability of animals and humans to synthesize the pantoic acid moiety of the vitamin. Pantothenic acid plays a primary role in many metabolic processes, such as oxidative metabolism, cell membrane formation, cholesterol and bile salt production, energy storage, and activation of some hormones (Miller et al., 2001).

Pantothenic acid deficiency in humans is rare because of its ubiquitous distribution in foods. Many health claims are made regarding the role of pantothenic acid in ameliorating rheumatoid arthritis, lowering cholesterol, enhancing athletic performance, and preventing graying of hair (Miller et al., 2001). However, sufficient information is lacking at this time and so firm recommendations may not be made. No reports of adverse effects of oral pantothenic acid in humans have been reported.

The Food and Nutrition Board (1998) established an adequate intake level (AI) for pantothenic acid of 5.0 mg/day for adult men and women, 6.0 mg/day during pregnancy, and 7.0 mg/day during lactation. As mentioned above, pantothenic acid is found in a wide variety of both plant and animal foods. Because of its thermal lability and susceptibility to oxidation, significant amounts are lost during processing. Rich food sources include chicken, beef, liver, and other organ meats, whole grains, potatoes, and tomato products.

**Biotin.** In mammals, biotin serves as a coenzyme for reactions that control such important functions as fatty acid metabolism and gluconeogenesis. Biotin is recycled upon degradation of enzymes to which it is bound. Biotin from pharmaceutical sources is 100 percent bioavailable. Deficiency is rare but has been seen in patients on parenteral nutrition without biotin supplementation (Zemleni and Mock, 1999). Lipoic acid and biotin have structural similarities, thus competition potentially exists for intestinal or cellular uptake. This may be of concern in settings where large doses of lipoic acid are administered or taken as supplements (Zemleni et al., 1997).

The Food and Nutrition Board established an AI for biotin due to insufficient data to set an RDA. Adult men and women have an AI of 30  $\mu$ g/day (FNB, 1998). It is the same for pregnancy and increases to 35  $\mu$ g/day during lactation. No adverse effects of biotin have been reported. Toxicity has not been reported in patients receiving up to 200 mg orally daily or up to 20 mg intravenously.

Biotin is distributed widely in natural foods. Those rich in biotin include egg yolk, liver, and some vegetables. It is estimated that individuals in the United States consume between 35 and 70  $\mu$ g/day.

**Choline.** Choline has been considered a nonessential nutrient because humans can synthesize sufficient quantities. However, when hepatic function is compromised, hepatic choline synthesis is decreased and thus choline is

now considered “conditionally” essential. In a 1998 report from the Food and Nutrition Board, choline is considered an essential nutrient (FNB, 1998). The Food and Nutrition Board noted that additional studies on the essentiality for human nutrition are needed. Specifically, the 1998 Food and Nutrition Board study suggested that graded doses of choline intake be studied regarding their effects on organ function, plasma cholesterol, and homocysteine levels.

Choline functions as a precursor for phospholipids and acetylcholine, and betaine. The AI for adult men was set at 550 mg/day and for women at 425 mg/day. For pregnancy, the AI was increased to 450 mg/day and during lactation, to 550 mg/day (FNB, 1998). Due to reports of hypotension (low blood pressure) from excess intake, a UL was set at 3.5 g/day for persons nineteen years and older. Choline and choline-containing lipids, mainly phosphatidylcholine, are abundant in foods of both plant and animal origin. Rich sources include muscle and organ meats and eggs. To date there are no nationally representative estimates of choline intake from food or supplements.

## Fat-Soluble Vitamins

**Vitamin A.** The active forms of vitamin A participate in three essential functions: visual perception, cellular differentiation, and immune function. A number of food sources are available for vitamin A. Preformed vitamin A is abundant in animal foods and provitamin A carotenoids are abundant in dark-colored fruits and vegetables. With a 2001 report from the Food and Nutrition Board (FNB 2001), there has been recognition of a change in equivalency values of various carotenoids to vitamin A. Retinol activity equivalents (RAEs) for dietary provitamin A carotenoids—beta-carotene, alpha-carotene, and beta-cryptoxanthin—have been set at 12, 24, and 24  $\mu$ g, respectively (see Table 1, below). This decision is based on an extensive review of studies, which are summarized in the FNB report (2001) (see Table 1).

A number of factors affect the bioavailability of carotenoids (Castenmiller and West, 1998). Percent ab-

TABLE 1

### Dietary forms of vitamin A and provitamin A carotenoids

Consumed	Absorbed	Bioconverted
Dietary or supplemental Vitamin A (1 $\mu$ g)	Retinol	Retinol (1 $\mu$ g)
Supplemental beta-carotene (2 $\mu$ g)	beta-carotene	Retinol (1 $\mu$ g)
Dietary beta-carotene (12 $\mu$ g)	beta-carotene	Retinol (1 $\mu$ g)
Dietary alpha-carotene or beta-cryptoxanthin (24 $\mu$ g)	alpha-carotene or beta-cryptoxanthin	Retinol (1 $\mu$ g)

SOURCE: Adapted from FNB 2001

sorption decreases as the amount of dietary carotenoids increases, and the relative carotene concentration absorbed increases when consumed with oil or associated with plant matrix material. That is part of the plant vitamin source, not separated out as a supplement. The presence of dietary fat stimulates the secretion of bile acids and improves the absorption of carotenoids.

Recommended dietary allowance for men is 900  $\mu\text{g/day}$  of vitamin A and for women 700  $\mu\text{g/day}$ . During pregnancy, RDA is set at 770  $\mu\text{g/day}$  and 1,300  $\mu\text{g/day}$  during lactation. Human infants consume about 400  $\mu\text{g/day}$  of vitamin A in the first six months of life (FNB, 2001).

Based on the literature review, the FNB used liver abnormalities as the critical adverse effect for setting the UL for adults. Issues of carcinogenicity were considered for women of childbearing age. The UL varies slightly with age between 2,800 and 3,000  $\mu\text{g/day}$  of preformed vitamin A in food or supplements for adolescents and adults. Note that alcohol intake enhances the toxicity of vitamin A.

The richest sources of vitamin A are fish oils, liver, and other organ meats. Whole milk, butter, and fortified margarine and low-fat milks are also rich in the vitamin. In the United States carrots, fortified spreads, and dairy products are the leading contributors of vitamin A to the diet.

**Vitamin D.** Vitamin D is essential for life in higher animals. It is one of the most important regulators of calcium homeostasis and was historically considered the “anitrachitic” factor. The biological effects of vitamin D are achieved only by its hormonal metabolites, including two key kidney-produced metabolites: 1,25(OH)<sub>2</sub> vitamin D and 24,25(OH) vitamin D. In addition to its role in calcium metabolism, research has identified that vitamin D plays an important role in cell differentiation and growth of keratinocytes and cancer cells and has shown that it participates in the process of parathyroid hormone and insulin secretion (Bouillon et al. 1995).

Vitamin D<sub>3</sub>, the naturally occurring form of the vitamin, is produced from the provitamin, 7-dehydrocholesterol, found in the skin under the stimulation of ultraviolet (UV) irradiation or UV light. Vitamin D<sub>2</sub> is a synthetic form of vitamin D that is produced by irradiation of the plant steroid ergosterol. A requirement for vitamin D has never been precisely defined because vitamin D is produced in the skin after exposure to sunlight. Therefore, humans do not have a requirement for vitamin D when sufficient sunlight is available. The fact that humans wear clothes, live in cities where tall buildings block the sunlight, use synthetic sunscreens that block UV rays, and live in geographical regions of the world that do not receive adequate sunlight contributes to the inability of the skin to synthesize sufficient vitamin D (Holick, 1995). Exposure to the sun sufficient for humans to obtain enough UV radiation to synthesize adequate vi-

tamin D can be as little as three weekly exposures of the face and hands to ambient sunlight for 20 minutes (Adams et al., 1982).

A substantial proportion of the U.S. population is exposed to suboptimal levels of sunlight during the winter months. Under these conditions, vitamin D becomes a true vitamin and must be supplied regularly in the diet. The Food and Nutrition Board recommend an AI or adequate intake of vitamin D at 200 IU/day (5  $\mu\text{g}$ ) for adults up to fifty years of age (FNB, 1997). For adults over fifty-one, the AI is set at 400 IU/day (10  $\mu\text{g}$ ).

To prevent life-threatening hypercalcemia, an upper level (UL) for vitamin D has been set at 2,000 IU/day (50  $\mu\text{g}$ ) for adults over age eighteen. The use of 1,25(OH)<sub>2</sub> vitamin D for treatment of hypoparathyroidism, vitamin D-resistant rickets, renal osteodystrophy, osteoporosis, and psoriasis opens the door for potential toxicity because this form of the vitamin is much more toxic and the body's metabolic controls are bypassed. When this medication is being used, careful monitoring of plasma calcium concentrations is required.

Salt-water fish are good unfortified sources of vitamin D. Small quantities are derived from eggs, beef, butter, and vegetable oils. Fortification of milk, butter, margarine, cereals, and chocolate mixes help in meeting the dietary requirements. Excessive amounts of vitamin D are not available in usual dietary sources. However, excessive amounts can be obtained through supplements that result in high plasma levels of 25(OH) vitamin D.

**Vitamin E.** Vitamin E (also called tocopherol) is found in cell membranes and fat depots. Because of their chemical structure, there are eight stereoisomers of each of the tocopherols. In addition to each of the stereoisomers, each occur in alpha, beta, gamma, and delta forms (FNB, 2000).

Its most recognized function is to protect polyunsaturated fatty acids (PUFA) from oxidation. PUFAs are particularly sensitive to oxidative damage, and the protective role of vitamin E is supported by a similar antioxidant protection from vitamin C and selenium. One tocopherol molecule can protect 100 or more PUFA molecules from autoxidative damage (Pryor, 2001).

The various forms of vitamin E have different biological activity, with the natural source isomer—*R,R,R*, $\alpha$ -tocopherol—being the most active. In supplements you may see this isomer called by its former name, *d*- $\alpha$ -tocopherol. Synthetic vitamin E is called *all-rac*- $\alpha$ -tocopherol or *dl*- $\alpha$ -tocopherol in supplements. Biological activities of vitamin E are given in the older international units (IU) or  $\alpha$ -tocopherol equivalents ( $\alpha$ -TE). Because of the many forms of vitamin E in plants and available synthetically, the relative activities of each form is complex. Current evidence indicates that vitamin E from natural sources has approximately twice the bioactivity in humans that the *all-rac* (synthetic) vitamin does (Burton et al., 1998).

Based on the literature review, FNB used hemorrhagic (bleeding) effects for the criteria to set the UL. For adults nineteen years and older the UL is 1,000 mg (2,326 mol)/day of any form of supplementary alpha-tocopherol. There is no evidence of adverse effects from intake of vitamin E naturally occurring in foods.

The RDA for vitamin E is 15 mg/day of naturally occurring alpha-tocopherol for adults above nineteen years of age (FNB, 2000). During pregnancy 15 mg/day is recommended and 19 mg/day for lactation.

The tocopherol content of foods varies widely depending on storage, processing, and preparation. The best sources of vitamin E are the common vegetable oils and products made from them. However, most of the tocopherols may be removed in processing. Wheat germ and walnuts also have high amounts of tocopherols.

**Vitamin K.** Vitamin K was named after the first letter of the German word *Koagulation*. For many years blood coagulation was assumed to be the sole physiological role for vitamin K. We now know that vitamin K plays an essential role in the synthesis of proteins including prothrombin and the bone-forming protein, osteocalcin (Vermeer et. al., 1995).

Dietary vitamin K absorption is enhanced by dietary fat and is dependent on bile and pancreatic enzymes. The human gut contains large amount of bacterially produced vitamin K, but its contribution to the maintenance of vitamin K status has been difficult to assess (Suttie, 1995). The vitamin K produced by bacteria in the gut is less biologically active even though it is stored in the liver and present in blood. Current understanding supports the view that this vitamin K source may partially satisfy the human requirement but that the contribution is much less than previously thought.

The drug warfarin, widely prescribed as an anticoagulant, functions through inhibition of vitamin K. As a result, alterations in vitamin K intake can influence the efficacy of warfarin. The effective dose of warfarin varies from individual to individual, as does the dietary intake of vitamin K. The best solution appears to be to establish the necessary dose of warfarin and urge patients to maintain a constant intake of foods high in vitamin K in their diets. Only a small number of food items contribute substantially to the dietary vitamin K.

The recommended intake is based on an AI or adequate intake of 120  $\mu\text{g/day}$  for men, 90  $\mu\text{g/day}$  for women, and 90  $\mu\text{g/day}$  during pregnancy and lactation (FNB, 2001). No adverse effects have been associated with vitamin K intake in humans from food or supplements. Thus, no UL is set for vitamin K.

Collards, spinach, and salad greens are high in vitamin K. Broccoli, Brussels sprouts, cabbage, and Bib lettuce contain about two-thirds as much, and other green vegetables contain even less. Vitamin K is also found in plant oils and margarine, with soybean and canola oils

having the highest amounts. U.S. food intake surveys indicate that spinach, collards, broccoli, and iceberg lettuce are the major contributors of vitamin K in the diet.

**VITICULTURE.** See **Grapes and Grape Juice; Wine.**

**WAFFLES AND WAFERS.** Waffles and wafers are like many other foods of ancient origin in that the name and the food described have separate histories that eventually merge into one. The wafer traces its origin to ancient Egypt, but the descriptive terms applied to it are generally of medieval origin. In Latin, *oblatao* and *oblatum* were used to denote cakes made with unleavened flour and water worked into a thin flat round or square sheet of pastry and baked until crisp. This Latin root meaning is still employed in many European languages, but with varied interpretations. In modern German, *Oblaten* are both communion wafers and sheets of paper-like material laid under gingerbreads or baked meringues to keep them from sticking to the baking sheet. In Polish, *oplatki* are communion wafers or any wafers resembling them in shape and texture.

In English, however, the root word stems from medieval German and Anglo-Saxon: *weben*, “to weave,” in reference to the crisscrossed pattern on the surface of the wafer. It appears in medieval Frankish as *wafel* and later in medieval French as *waufre*, now written *gaufre*, with the diminutive *gaufrette*. *Gaufre* can also be a honeycomb and in that sense may refer to an ancient pattern imprinted on certain wafers. This same honeycomb design is found on Coptic ritual breads in Egypt and may relate to an extinct votive wafer or flat bread sweetened with honey. Its modern survival may be the Swiss *Tirggel*, a type of honey wafer imprinted with a wide variety of ornamental images.

The wafers of ancient Egypt were prepared from only the finest wheat flour (actually the flour of emmer, a species of primitive wheat). Athenaeus of Naukratis attributed the origin of the wafer’s name (*obelias*) to the fact that it cost one *obel* (a thin Greek coin). Since this “fact” was drawn from a literary source, it may well be pure folk etymology. As Otto Meinardus has pointed out repeatedly in his seminal work on early Coptic Christianity, there is a far more fundamental dimension to the wafer since the grain from which it was made was treated as the actual “body of Osiris” (Meinardus 1964 and 1999); thus those who partook of the ritual wafers were said to live by the body of their god. This concept was carried over into Christianity in two forms: in the *oblata hosta* employed as the bread of communion in the Latin church

(due perhaps to its similarity in shape and function to ritual bannocks), and in the *fetir* (leavened flat bread), *dubn* (unleavened flat bread), and *qurban* (communion loaf) of the Coptic church. All three Coptic breads may be stamped, although it is mainly the *qurban* that serves as the ritual link to pre-Christian Egypt by virtue of its employment as communion bread. This bread, prepared only by monks from the finest wheat flour, is stamped with a wooden form to create the honey-comb pattern also found on wafers. This pattern is sometimes described by art historians as interlocking crosses.

In addition to the New Testament associations of the communion bread, the Copts also believe that Adam received grains of wheat from the Archangel Michael and therefore must honor god with bread offerings. The Feast of St. Michael on 12 Hatur (21 November) is one of the major Coptic feasts for which a large number of ritual breads are prepared. Thus, some of the earliest depictions of both wafers and round loaves stamped with wafer patterns can be found in Coptic art honoring this saint.

The introduction of the ritual wafer into the West cannot be accurately dated, although in the form taken over by Christians, it may have arrived in connection with the cult of Osiris once found throughout the Roman Empire. It survived solely as a key element of the Latin Eucharist and remained a point of contention with Eastern Orthodoxy, which claimed that the Christ intended leavened bread for the Eucharist. Jacobite Christians even claim to preserve the original sourdough starter.

During the Middle Ages, communion wafers were made by monasteries, which also sold them as a form of fasting food, since they contained no animal fats, eggs, or dairy products. It is evident, however, that the composition of wafers could be elaborated with expensive ingredients like saffron, sugar, and various spices for the benefit of the nobility and other classes of society willing to pay a higher price for a more pleasurable form of self-denial. By the 1200s wafers were well integrated into courtly cuisine and form one of the standard dessert foods served at banquets. One of the earliest references to this appears in the 1285 Anglo-Norman “Treatise of Walter of Bibbesworth,” which includes dinner menus set to verse. In one menu, the meal ends with “plenty of wafers” (*oubleie a fuissun*). These were probably sweetened with

Wafer iron for stove-top baking. Made by the Werle Iron Foundry, Ottweiler (Saarland), Germany, ca. 1840–1870. Cast iron. The underside of the wafer depicts the traditional *waben* or “woven” texture while the topside is ornamented with snails, flowers, and hearts. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

sugar from Cyprus and flavored with saffron, since sweet saffron wafers are mentioned many times in medieval manuscript cookery books.

Wafers also played a significant role in localized religious observances in many parts of Europe. In Franconia (a subdivision of modern Bavaria), wafers were especially important on Ascension Day and Pentecost. On Ascension, for example, the *Auswerfung des Himmelbrots* (showering the manna) was practiced, whereby priests threw wafers and other treats down from the “sky” painted on the church ceiling in imitation of manna falling from heaven—this after a figure of Christ was hoisted up through a trap door as though rising into the clouds. In Alsace, communion wafers were purchased from monasteries and used to ornament the earliest known Christmas trees. In most cases, these wafers were

ornamented with religious pictures, Christian symbols, or a simple cross.

Since wafers could be consumed as fasting fare, there was considerable demand for them in towns and cities. This demand led to the secularization of wafer manufacture as a specialized craft organized into guilds. Wafer makers also altered the pictorial imagery employed on wafers, introducing scenes from fables, classical antiquity, coats-of-arms, or symbols of love. Thus the wafer moved from a purely religious context to a middle-class form of dessert, especially for festive occasions. By the 1600s, the irons used to make wafers were commonly found in the homes of well-off burghers, and many Dutch, French, German, Spanish, and Italian still life paintings show wafers, especially those rolled into tubes, scattered among the foods on richly appointed tables. These festive wafers

acquired numerous names all over Europe, such as *pizzelle* in Italy, *Eiserkuchen* (iron cakes) in some parts of Germany, or in Holland *Nijarskouk* (New Year's cake). Elsewhere they were called Twelfth Night wafers and were even stamped with fantastic masks or printed with molds to resemble playing cards—this latter motif popular in Switzerland.

Wafers rolled into tubes were not an invention of the Renaissance even though they became popular at that time. The concept is said to trace to the Christians of Syria who were especially well known for their filled pastries during the Byzantine period. One type of wafer was first wrapped around sticks of sugar cane to dry, then removed, filled with various rich mixes of mashed fruit or cheese, and fried or baked. These confections were taken to India by the Syrian Christians who settled there and were continued by the exiled Syrians living in Cyprus during the de Lusignan dynasty (1291–1489). Wafers filled with jelly or used sandwich style for fruits cooked in wine and mashed, continued to be popular as Christmas confections in Europe well into the nineteenth century. Bent into cones, they were used to hold various sweets, and this idea was the basis for the now ubiquitous ice-cream cone commercialized at the U.S. Centennial in 1876.

The waffle is a later offshoot of the basic wafer idea, but taking it to an opposite extreme. Where the wafer served as a metaphor for fasting and self-denial, the waffle became the Protestant symbol of festive luxury. Made with eggs, cream, and other rich ingredients originally forbidden during fast days, the waffle evolved as a type of fat cake baked between irons in imitation of *pain perdu* or French toast. It first appeared in the Low Countries in connection with Christmas, New Year's, Twelfth Night, and Carnival, employing the distinctive honeycomb pattern to render it crispier than a deep-fried slice of toast. Like wafer irons, waffle irons were often given as wedding gifts, and it was the Dutch who settled in New York who brought the waffle custom to North America, for it was otherwise not well known to the English.

In the United States, waffle irons appeared in many eighteenth-century household inventories, especially those of well-to-do families. The popularity of waffles as a special occasion dish (for Sunday breakfast, for example) or as Christmas and New Year's confections gradually spread so that by the Civil War, waffles were available in most hotels, especially as a breakfast or supper food served plain or in combination with various meat fricassees. Ham gravy, chicken gravy, waffles made with a sweet potato batter, all of these and many more permutations appeared on hotel menus. By the early 1900s, once the automobile and the Sunday drive came into fashion, such main course waffle dishes were integrated into the menu of local tourist destinations catering to the Sunday clientele. Waffle dinners of the 1920s and 1930s even become a form of fund-raising for churches and fire companies.

Hot coffee and waffles are popular high-energy breakfast fare in both Europe and America, especially at ski resorts. PHOTO TAKEN AT A FARM KITCHEN OPEN TO SKIERS IN HAFJELLET, NORWAY. © ADAM WOOLFITT/CORBIS.

The electric waffle iron, which first appeared in the 1890s, became a popular tool of the home economics movement, and a popular wedding gift by the end of World War I. It brought the eat-out experience full circle into the home not just for its convenience, but by lowering the perceived cost through boxed waffle mixes, canned gravy preparations, and the like. The processed waffle, entirely pre-made and frozen so that can be cooked in toasters or the microwave oven, is now the supermarket descendant of the rich confection of former times. The fat-free waffle with its New Age ingredients and designer flavors may not evoke a breakfast fit for kings. On the other hand, the costly honey drizzled over it, now imported from the Amazon jungle, can only provoke wonder from the gods of old, whose honeycombed cakes were once a metaphor for eternal life.

**WAITERS AND WAITRESSES.** The career of the waiter and waitress begins with the industrialization of food. Prior to that, women dominated food preparation and serving in most cultures, and this may have reinforced the suspicions of them as dangerous. Polluted or poisoned foods have been a style of murder favored by women. A notorious poisoner was the Marquise de Brinvilliers (1630–1676) who claimed that half the French court of Louis XIV was engaged in attempted murder. Before her, there was Agrippina (15–59 C.E.), Lucrezia Borgia (1480–1519), and Catherine de' Medici (1519–1589), who have each been associated with such acts.

### The Trusted Sex

In court societies, before the regulations introduced by the modern bureaucratic state, chefs, waiters, and food handlers were appointed by the monarch, and this served as an endorsement of trust. In the modern era, with refrigeration and scientific forensics, the incidence of food pollution and poisoning has dramatically dropped. At the same time, men have entered the food business and become celebrated chefs and restaurateurs. This is not to imply a causal relationship, but an interesting association of gender and status, borne out with examples from the formal restaurants of the late nineteenth century, where respectable women were not allowed as guests but could work—in lowly positions—and where only males were trusted with the job of waiter. They were required to justify that trust by wearing white gloves while serving to demonstrate that their fingers had not slipped into the sauce and then been licked clean.

### Waiters and Power

Many pleasures of dining out relate to service and luxury. In the formal restaurant, diners have temporary possession of elegant silverware, crystal and tableware, and

## TIPPING

The origins of the term may be the phrase—To Insure Promptitude—or from the slang "tip," to give. Tipping now operates as a tacit rule in most restaurants other than the fast-food chains and large-scale, self-service canteens. However, even though tipping is almost universal, the rules governing it are not. In the early part of the twentieth century, etiquette manuals offered lengthy advice about it, thereby indicating that it was a problematic exchange in a new, liberal era. Current tourist guides simply state that it is expected, even when there is a service charge already included. The iconic metropolitan comedian, Jerry Seinfeld, tells his urbane New York City audience that we tip in order to prevent violence, such as having our heads smashed into the glass-top table or being chased up the street by the "stiffed" waiter.

the command of others. George Orwell (1933) declares that one should never feel sorry for the waiter who stands by, watching and attending to the pleasures of diners. The waiter is a snob and thoroughly understands the attractions of the experience and wishes only for the opportunity to act exactly as the diner is doing.

There are various contests for power and privilege going on in this setting. Orwell gives the example of personal appearance: the chef wears a moustache to display rank and show contempt for the waiters who do not wear a moustache, who in turn show their superiority by refusing to allow the *plongeur* or dishwasher to wear a moustache. Gerald Mars and Michael Nicod (1984) note the many strategies and tactics employed by waiters, diners, and management to gain advantages over one another. Each of them struggle, using tipping, fiddling (pilfering), and cutting corners, to display their superior status and power to one another.

### Service

The great divide between American and European restaurant styles emerges with the industrialization of food, dating from the end of the nineteenth century, when grocery stores (then, supermarkets), factory production, mass marketing of snack foods, and fast-food and chain restaurants began to transform a minor retail activity into a major economic market. American women worked in restaurants after the 1940s (Pillsbury, 1990), making them less formal and more relaxed. Dolores Dante, a waitress of twenty-three years (Terkel, 1972) reported on the pride she took in her work despite the

Final exam for a waiters' school in Berlin, from a wood engraving circa 1880. The parents of the young men watch as they are clocked to set a banquet table in five minutes. ROUGHWOOD COLLECTION.

taunts and insults received from male clients, who mistakenly used the threat of not tipping as a way of gaining her attention and service.

The role of the waiter and waitress has held constant fascination for novelists and social investigators, all of whom comment on the highly charged relationship between the diner and waiter. In formal restaurants, knowledgeable waiters can intimidate diners they consider out of place or presumptuous. Lone women diners, or those with young children, for example, may find the formal restaurant inhospitable because the waiter expects a negligible tip and judges them not to be worth their effort. In short, the pleasures of dining out rest largely on the performance of the waiter.

### American Economics vs. European Craft

Americans mostly favor small diners, self-service, or fast-food chain restaurants where the level of service is low and the expectations of customers limited. At the other end of the spectrum, there are prestigious, celebrated, and expensive restaurants where the waiter is required to indulge the demands of diners. Between these extremes is the increasingly popular range of casual restaurants and bistros that often advertise themselves as emulating the

more luxurious restaurants. However, in doing so, they create expectations in their customers which, in reality, they cannot deliver. The waiter (and more often waitress) in such restaurants is caught between the efficiencies demanded from the restaurant management and the customers' expectations. In this gap, waiters and waitresses learn short cuts; they may finger the food in order to improve the presentation on the plate; wipe off dirty dishes and cutlery rather than replace them; dilute coffee by making two from one serve and so on. The waiter is caught in a perennially conflict-infused relationship with the management, chef, and diner over presentation, quality, and speed of service (Hughes, 1958; Whyte, 1949).

Dining in America can be theatrical, with gimmick and theme restaurants that require waiters and waitresses to deliver food on roller-skates or to dress in colorful uniforms or theme costumes. With such attractions and diversions, the American restaurant locates itself within the entertainment industries. Accordingly, the waiter or waitress is a performer, spruiking the attractions of the menu, providing amusement, and creating the illusion of service. (Spruiking is a style of advertising in which the waiter is trying to convince his customer about the delights of a certain portion.) Included in the job might be

salary incentives for selling the greatest numbers of desserts or menu specials. The European waiter does not traditionally work in such an environment where the numbers of clients and settings determine his salary. The waiter's interests are to enhance the pleasures of eating; thus a European diner in a formal restaurant expects the waiter to demonstrate impeccable manners and elegant style, and not to promote certain dishes. A greater degree of informality exists between the American diner and waiter; more conversation takes place that has little to do with the food and menu and more to do with the sociability of the event. The displays of food craft from waiters such as carving meats, serving portions at the table, and setting cutlery, have largely vanished from the restaurant scene in America, and only re-emerge now and then as part of the entertainment of dining in expensive, formal, elegant restaurants.

#### WATER.

*This entry contains three subentries:*

Water as a Beverage and Constituent of Food  
Water as a Resource  
Safety of Water

#### WATER AS A BEVERAGE AND CONSTITUENT OF FOOD

The human body has a water content that represents from 65 to 70 percent of its total mass. This means that a 70-kilogram (154-lb.) adult male has a fluid content of 45 to 50 liters of water. Only 3.6 to 4.0 liters or 8 percent of

this fluid is in the bloodstream. Of the body's total water content, 60 to 70 percent is within the cells, and an additional 20 percent is in the intercellular space. These fluid compartments differ with respect to certain important constituents such as ions (electrolytes) that play an important role in cell function. The maintenance of homeostatic balance in each of these fluid compartments requires finely tuned interactions of the endocrine system and the organs involved in the absorption and excretion of minerals and other nutrients. The chemical properties of the food and water consumed can have profound effects on the function of the organs maintaining this balance. An extreme example of imbalance with fatal consequences is the dehydration that follows the consumption of salty seawater. When this occurs, the kidneys are forced to increase urine production to rid the body of the excessive salt, with the result that blood and intercellular fluid volume are reduced. In extreme cases such loss can disrupt fluid homeostasis sufficiently to result in death.

#### Hydration

Humans differ from other primates in relying heavily on evaporative cooling achieved through the sweat response to maintain normal body temperature under increased heat loads. Sweat contains proteins and minerals in addition to water. Heavy, sweat-inducing exercise, especially under warm, humid conditions and in untrained individuals, can result in the loss of excessive salt in sweat. Water loss exceeding twenty liters per day, sometimes as much as three liters per hour, can result from vigorous exercise under desert conditions. Replacement of fluids under such circumstances often requires forcing fluids since the human thirst response lags behind actual requirements, resulting in what has been termed "voluntary dehydration."

Athletes engaged in ultra endurance competition are especially subject to the risk of dehydration, since they typically do not satisfy their fluid requirements while exercising. On the other hand, forced consumption of plain water can, under such circumstances, result in overhydration. Insufficient salt intake can also produce a serious impairment of performance. Under such circumstances, fluids containing electrolytes are necessary to sustain performance. In addition to electrolytes, glucose, or glucose-containing carbohydrates, can enhance water absorption as well as supply supplemental energy for muscle metabolism. However, a carbohydrate concentration exceeding 5 percent weight per volume may actually reduce the rate of water absorption (Rehrer, 2001). Athletic training for endurance competition routinely includes emphasis on increasing the ability to consume sufficient fluids.

#### Minerals in Water

In addition to their needs for energy, proteins, and fats, humans require a number of vitamins and minerals. Some of these nutrient requirements, especially those for minerals, can be partially and sometimes totally satisfied

through the consumption of drinking water (Costi et al., 1999). The water people drink varies greatly from one area to another. Some communities rely on surface water drawn from rivers and lakes, often stored in reservoirs. Other communities rely on groundwater drawn from subterranean aquifers. Both surface water and groundwater can bear significant loads of salts and other minerals. Water purification systems are usually designed to keep the salinity of drinking water within prescribed limits in areas where water supplies tend to be salty. However, sodium can be detected in most water supplies, sometimes in surprisingly high concentrations. In cities such as Jiddah, Saudi Arabia, that depend entirely on desalinated seawater, the salinity of the drinking water is quite noticeable to the visitor.

Because of its unique chemical properties, water is seldom if ever found in its pure state. Even rainwater contains contaminants absorbed from the atmosphere while in the vapor phase and during its descent to Earth in its liquid phase. However, rainwater is generally considered to be “soft water,” since its mineral content is lower than that of most other sources. Water “hardness” is often associated with its calcium content, since drinking water is drawn from aquifers associated with limestone deposits in many parts of the world. In these areas precipitated water percolates through topsoil rich in organic compounds, becoming increasingly acidic in the process. When this acidic water comes into contact with the calcium carbonate of the limestone bedrock, it gradually dissolves the rock and carries its soluble constituents with it into the aquifer. Depending upon the length of time over which this process occurs, the water that finally finds its way into the aquifer can carry a substantial load of calcium and carbonates. Such water may require “softening” if it is to be used to launder clothing, since it tends to precipitate soaps. However, hard water of this sort is potable and may indeed be considered quite desirable as drinking water.

### Sources of Drinking Water

While the palatability of drinking water is literally a matter of taste, it is unlikely that pure, distilled water would be considered a desirable beverage. When comparisons of drinking water are made, the samples generally considered most desirable are invariably ones that bear a significant mineral content. For example, the drinking water of New York City, piped in from reservoirs in upstate New York, is considered of superior taste as a result of its mineral content. In other parts of the United States, groundwater drawn from ancient deposits is considered a precious but diminishing resource. A case in point is that of Tucson, Arizona, where Pleistocene water deposits are being withdrawn at a rate faster than normal recharge. Consequently the growing needs of this urban area are projected to be satisfied through increasing use of Colorado River water diverted to Phoenix and Tucson by the Central Arizona Project (CAP). Community resistance to the use of Colorado River water has resulted in a program focused on the “blending” of groundwater

*The Water Carrier*, nineteenth-century painting by Mexican artist Edouard Pingret. In the age before indoor plumbing, the water carrier was the primary source of drinking water in most cities and towns. Private Collection, Mexico. © ARCHIVO ICONOGRAFICO, S.A./CORBIS.

with CAP water in an effort to avoid an abrupt change in the perceived quality of the drinking water.

The features of CAP water that have most troubled the Tucson Water Authority are the substantial load of sediment it bears as well as its different mineral composition. The expense of purification to achieve a standard comparable to that of the Pleistocene groundwater long taken for granted has been prohibitive. In an initial attempt to convert to exclusive use of CAP water in a number of Tucson neighborhoods, tap water was found to be turbid, and according to many residents, it had a distinctly unpleasant flavor. It was eventually determined that part of the problem arose from the release of mineral deposits from the water pipes both within and outside residences subsequent to sustained exposure to water having a significantly different chemical profile. The release of these deposits sometimes caused leakage that resulted in property damage and claims for compensation. The problems encountered by the Tucson Water Authority were the result of an unusual set of circumstances coupled with concern for the damage that could occur if the depletion of the local groundwater supply should progress to a point where subsidence caused structural damage to buildings. Concern for the risk of subsidence was

Traditional *cantaro* or water jar. Nicaragua, twentieth century. Brownware pottery. This ancient Mediterranean form was brought to the New World by Spanish settlers. It is still common in Central America. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

well-founded, since parts of Interstate 10 less than fifty miles from Tucson have required repeated repair due to damage directly attributable to subsidence.

The problem of subsidence is of concern in many parts of the world where increasing need for drinking water has led to the depletion of aquifers. It is a concern in the central United States, for instance, in an extensive area overlying the Ogallala Aquifer. Although the falling water table in this region is largely the result of agricultural use of water, urban growth has had a deleterious impact on aquifer recharge with the result that drinking water supplies are increasingly drawn from surface water sources. The long-term consequence is a decline in both the quality and quantity of drinking water in a number of cities. In coastal areas, depletion of aquifers has led to saltwater incursions that seriously impact the quality of drinking water. As is sometimes the case in midcontinental regions, damage to aquifers in coastal areas can be irreversible, necessitating reliance on alternative sources of drinking water. In the event of a rise in sea level associated with global warming, such reliance will become increasingly widespread. In almost every case the mineral profile of the alternative source will differ from that of the original groundwater, often in ways that alter the taste of drinking water.

## Contaminants

Reliance on surface water sources for drinking-water supplies presents numerous problems. Surface water is subject to forms of contamination not usually found in groundwater. During the time it takes for water to percolate from the surface into the aquifer, most of its organic contaminants are left behind. Generally minerals take their place. The array of minerals present in the soil and bedrock determine the character and taste of the groundwater. As a rule the oldest deposits are the deepest. Therefore water pumped up from deep wells is less likely to bear organic contaminants. Additionally, deep wells provide a more stable supply of water since they draw on supplies that are less dependent upon recharge to maintain a constant flow. Shallow wells, such as the tube wells in many parts of Asia, for the most part trap surface water during a rainy season for use during the dry season. Water from such wells resembles surface water more than groundwater and may therefore contain a substantial load of organic contaminants.

The organic contaminants found in the surface water in many parts of the world include agricultural fertilizers and pesticides. Agricultural runoff, which finds its way to the larger streams and rivers before eventually reaching the oceans, contaminates freshwater bodies at all points along the line. In many cases the rich mixture of organic fertilizers entering lakes and rivers stimulates the growth of microorganisms, such as algal blooms. Eutrophication, the overgrowth of algae and other plant life, depletes the water of oxygen. Oxygen depletion limits the range of aquatic species that can inhabit these bodies of freshwater. The eutrophication of freshwater lakes is a serious problem in many parts of the world. It has a serious impact on the quality and quantity of drinking water wherever it occurs.

At least in part because of general distrust in the quality of drinking water, the consumption of bottled water has increased. The commoditization of the drinking-water supply is a fairly recent phenomenon in many parts of the industrialized world. The quality of water available from this source is highly variable. Some is drawn from mountain springs, where the mineral content is consistent and organic contaminants are virtually absent. Other commercially marketed bottled water comes from more dubious sources and may contain a variety of contaminants, including pathogenic organisms in unacceptably high concentrations.

Certain mineral waters, especially those purported to have therapeutic value, have long had a market. These mineral waters were originally consumed at their sources, often at spas, where hot springs produced highly mineralized, often sulfurous water thought to have medicinal properties when consumed or used as a bath. The Romans sought thermal springs throughout the areas they occupied in Europe, and they constructed baths that served as focal points of the communities.

The Romans were well aware of the benefits of a reliable supply of pure drinking water even in the absence of thermal springs, as the many aqueducts in Europe attest. The Romans did not face the problems associated with chemical contamination that accompany modern agricultural methods. However, they were aware of the risk of disease associated with contaminated drinking water and consequently preferred to draw their water supplies from mountain sources whenever possible. To what extent this preference reflects awareness of superior taste as a beverage is not known with certainty, but Roman literature includes many references to the desirable properties of the drinking water in specific parts of the empire.

The widespread marketing of drinking water in industrialized countries reflects in part an increasing awareness of the risks of contamination of conventional sources. This awareness comes at a time of increasing concern for the future supply of potable water for a steadily growing world population. Clearly, water is a basic requirement of life. Freshwater is not evenly distributed over the face of the planet. It is most abundant in places where few people live, and the transport of large amounts of water to the arid and semiarid areas of high population density presents a serious technological challenge. Contamination, both by chemical agents and by pathogenic organisms, is a problem that requires serious attention at every governmental level. Even in the United States, where the safety of the drinking water supply is usually assumed to be assured, occasional events, like the outbreak of a waterborne disease in Milwaukee, point up the fact that surface water supplies in particular are vulnerable. However, recognition of the urgency of the problem has increased public awareness of the necessity of preserving and protecting a fundamental resource, and it appears that drinking water is receiving the level of appreciation it deserves.

## WATER AS A RESOURCE

The central role played by water in the origin of life has long been acknowledged. As early as the seventeenth century, geologists recognized the extent to which water shaped and reshaped the landforms on the earth's surface. More recently, it has been argued that water plays a fundamental role in the formation of stars (Nisini, "Water's Role in Making Stars"). According to this account of the process of star formation, water may be present in two of its physical states, ice (a solid), and water vapor (a gas) in the earliest stages of the birth of a new star. During this phase, ice on the surface of dust particles contributes to the cooling of circumstellar gases by removing excess energy released during protostellar collapse. At the same time, water vapor serves as a reservoir of oxygen in the warmer sectors of accumulating mass. Certain of the peculiar physical and chemical properties of water to be discussed later make water uniquely qualified to participate in this seminal cosmological event.

Since stars form as the result of the gravitational collapse of dense molecular clouds, almost all of the water present in its earliest stages is found in the ice coats of dust grains. A small amount, however, is produced as vapor through a series of reactions beginning with  $\text{H}_3^+$  and O and resulting in the formation of  $\text{H}_2\text{O}$  and  $\text{O}_2$ . As star formation proceeds and gravitational collapse accelerates, increasing amounts of radiation energy are released. Consequently, the ambient temperature rises dramatically, and the temperature of the dust grains attains a level where water is released by evaporation. As the temperature continues to rise, all available atomic oxygen is rapidly transformed to water by the following reactions:

1.  $\text{O} + \text{H}_2 \longrightarrow \text{OH} + \text{H}$
2.  $\text{OH} + \text{H}_2 \longrightarrow \text{H}_2\text{O} + \text{H}$

As the process of star formation moves into its later stages, these equations are reversed with the release of OH and atomic oxygen. However, some of the water produced is deposited on dust grains in the form of ice, where it may remain while planets are formed. Thus, newly formed planets have continued access to water during their evolution. Within our own solar system, there is considerable evidence that liquid water was abundant at some earlier stage in the history of Mars. The erosion patterns still visible on the planet's surface bear a striking resemblance to some found on earth. Many astronomers are also convinced that liquid water is still present on Saturn's moon, Titan, and under a deep layer of ice on Jupiter's moon, Europa.

### The Reshaping of Landforms

Geologists have long been aware of the role water plays in the reshaping of the earth's surface. The uniformitarian theory of the earth's history explicated by Charles Lyell in the early nineteenth century recognized that the surface of the earth is essentially a chronicle of its reshaping by water erosion. Some of the most informative

strata for the reconstruction of past events are those that contain sedimentary deposits. These deposits, formed in lake beds and ocean floors, often contain fossils of species extant at a specific time, and can therefore be used, along with chronometric methods, to estimate the age of a given deposit and its contemporaneity with other deposits bearing similar fossils.

The formation of sedimentary deposits provides one of the bases for determination of relative dating sequences through the comparison of fossil inclusions. However, it is the gradual wearing down of mountains and other landforms by rain and snowfall and the transport of particles of rock and soil to the sea that are continually altering earth's topography. Water erosion, combined with tectonic forces at work beneath the earth's crust, is ultimately responsible for environmental changes that occasionally trigger major evolutionary events. In some areas, such as the Grand Canyon of Arizona, long sequences of the earth's history can be reconstructed through examination of strata exposed by the action of Colorado River water.

When major geological events such as the collision of tectonic plates occur, marine deposits sometimes end up in mountains, while other segments of the sea floor may be returned to the magma layer in zones of subduction. Mountain building may have profound effects on rainfall patterns. Under the appropriate circumstances, alterations in atmospheric conditions associated with major events such as the collision of the plates that joined the Indian subcontinent to the Asian landmass have the potential to trigger significant climatic changes. Changes in rainfall patterns, glaciations, and altered temperature gradients may be implicated in the onset of epochal events such as the Pleistocene "Ice Age," with worldwide effects on the evolution of plant and animal species.

### Water and Weather

The possibility of a worldwide change in climate associated with the rapid building of a major mountain range arises from the central role that the oceans of the earth play in the distribution of heat energy received from the Sun. Approximately 70 percent of the earth's surface is covered by water. Because of the tilt in the earth's axis, the waters of the equatorial zone receive the Sun's radiation more directly than areas in the higher latitudes. Consequently, more of the wavelengths of solar radiation that are subject to reflection, scatter, or absorption in the atmosphere actually reach the earth's surface in the tropics. Much of their energy serves to warm the oceans. The energy so received sets up warm ocean currents that flow away from the equatorial zone. Ultimately, the warm currents flowing out of the tropics mix with colder currents originating in the polar regions, but not before heat energy has been widely distributed over the oceans and landmasses of the temperate zones.

The warming of the oceans in the equatorial zone has the additional effect of evaporating ocean water.

Thus, water vapor enters the atmosphere. In the tropics, some of the moisture-bearing warmed air rises until it is sufficiently cooled to form precipitation. The result is the return of fresh water to the surface. The circulation of moisture-bearing atmosphere through the action of thermal gradients and prevailing winds allows some of it to flow to the cooler, drier areas at higher latitudes as well. Thus, the supply of fresh water is continuously replenished on the continental landmasses of both the Northern and Southern Hemispheres. The large number of plant and animal species that require access to fresh water for survival is evidence that the distribution of fresh water through the atmosphere has played a major role in the evolutionary process.

The mixing of ocean waters and the direction of currents produce a complex pattern that is influenced by factors beyond the dissipation of heat energy absorbed in the tropics. The salinity of seawater varies from one area to another according to the amount and composition of the silt emptied into the oceans by rivers and streams. Since very salty water is heavier than fresh water, streams of water flowing away from the mouths of rivers tend to sink. This tendency sets up a network of crosscutting currents that affect the temperature of water at various depths. Temperature and salinity both affect the mix of marine organisms present in the ocean biome (ecological community). Generally, estuaries are some of the richest and most diverse of the marine habitats. Exploitation of fisheries such as the one that formerly produced abundant catches of sardines in the Mediterranean Sea off the mouth of the Nile River provided local human populations with an important source of dietary protein for many millennia. Other areas, such as the zone of nutrient upwelling off the west coast of South America, are illustrative of the way in which the combination of geological factors and ocean currents can create a major source of food for human populations that have learned how to exploit them.

Although the vast majority of the earth's water is too salty to drink for many animals, including humans, evaporation and precipitation provide a constantly renewing source of fresh water. In addition, the atmospheric recirculation of water modifies the climate in the higher latitudes to such an extent that life can exist in areas that would otherwise be uninhabitable. Moreover, along with rainfall, atmospheric circulation plays an important role in the carbon cycle and nitrogen fixation, both essential to the maintenance of life.

### **The Physical and Chemical Properties of Water**

Through its role in the formation of stars, the reshaping of the earth's surface, the absorption and release of solar energy, and the provision of marine and aquatic habitats, water is essential for the existence of life as we know it. However, as important as each of these factors has been in shaping the evolutionary pathways that produced contemporary species, the physical and chemical properties

of water have resulted in a much more intimate relationship between water and the processes of life than the mere provision of an appropriate environment. Water molecules and the molecules of living organisms interact in ways that would make the existence of life, as we know it, inconceivable in the absence of water. Understanding the nature of certain properties of water provides important insights into the nature of life itself, since organisms can quite properly be categorized as aqueous chemical systems.

Water has an unusually high boiling point, melting point, and heat of vaporization. Thus, the transition from solid to liquid and liquid to gaseous phases requires a high energy input. Functionally, this attribute makes water an effective heat absorber. The aforementioned capture and distribution of solar energy by the oceans is one result of this attribute. Moreover, the density of water is greatest when it is in its liquid phase. Therefore, ice floats. The formation of a layer of ice on the surface of a lake or pond serves as insulation for the water beneath it, with the result that aquatic life can continue even through the long, cold winters of the higher latitudes. While it is certainly possible for small bodies of water to freeze solid during prolonged periods of severe cold, most large, deep lakes and rivers sustain a thriving population of fish and other aquatic species through even the most severe winters.

Water molecules have a strong attraction for each other. Therefore, water has surprisingly high surface tension and exhibits the properties of cohesion and adhesion. Its ability to form hydrogen bonds is extraordinary. This ability comes into play in a variety of ways during many biochemical reactions. Water's tendency to adhere to a surface and to attract other molecules underlies the biologically important process of capillary action whereby water has the capability of moving against the force of gravity under certain circumstances. An illustration of this capability is seen in the capillary action that pulls water from soil through the roots and ultimately to the leaves of even the tallest trees.

Water is also a very effective solvent. In fact, it is so effective in the dissolution of other substances that it is only rarely present in the pure, unadulterated state. The solvent properties of water have significance in both the geochemical and biochemical context. The nature and rate of erosion occurring in different kinds of rock will produce changes in the physical geography of the land as well as the chemical nature of silt borne by rivers and streams. The dissociation of mineral compounds can be of special significance when the solute is one of a number of salts that dissociate into ions in water. Ionization of salts converts water into an effective conductor of electricity. Many biological processes, including transmission of nervous impulses and contraction of muscle fibers, depend upon a mild salt solution's ability to conduct an electrical current under controlled conditions.

The explanation for the extraordinary properties of water can be found in its previously mentioned

unparalleled ability to form hydrogen bonds. Structurally, an individual water molecule is made up of two hydrogen atoms covalently bonded to one oxygen atom. That is, each hydrogen atom shares a pair of electrons with the oxygen atom. As a result, the molecule has a nonlinear shape and has electrical polarity because of a net positive charge on the hydrogen atoms and a net negative charge on the oxygen atom, creating a dipole moment. Water can serve as both a hydrogen donor and a hydrogen acceptor during hydrogen-bond formation, with each water molecule having the potential to form four hydrogen bonds. The intermolecular attraction inherent in this property accounts for water's high boiling point, melting point, heat of vaporization, and surface tension. The hydrogen bonds between water molecules are relatively weak and are continually broken and reformed with different partners. In liquid water, the average lifetime of the hydrogen bond between two water molecules is only  $9.5 \times 10^{-12}$  seconds (Garrett and Grisham, 1999). As a result, there is dynamism in a water solution that intensifies the diffusion of the products of dissociation. This continuous movement of water molecules enhances its solvent effect. Water also forms hydrogen bonds with a wide range of polar solutes. This permits nonionic but polar molecules such as sugars also to dissolve effectively in water.

Certain nonpolar substances, categorized as hydrophobic, interact with water much differently than the hydrophilic ones discussed up to this point. When such substances are dissolved in water, the surrounding water molecules reorganize to encapsulate the solute molecules in a hydration shell. Hydrophobic molecules trapped in these structures are attracted to each other. The tendency of fats and oils, both hydrophobic in nature, to form closed aggregations when submerged in water arises from this tendency. On the other hand, the tendency for oil to spread out into a thin film when poured on the surface of water reflects its hydrophobic nature in a situation where the lowest free energy state occurs when each molecule has minimum contact with neighboring water molecules. The composition of cell membranes, which characteristically combine a hydrophobic phospholipid bilayer with hydrophilic protein and carbohydrate receptors, provides an example of the manner in which the presence of an aqueous environment can be used to govern the movement into and out of the cell's interior.

### Life Requires the Presence of Water

All living organisms require the presence of water to satisfy their metabolic needs. Even in such simple organisms as bacteria, metabolic processes requiring maintenance of solute concentrations inside the cell membrane that differ from those outside are essential to survival. In more complex organisms, the ability of water to absorb and diffuse solutes, create a potential electrical charge, and diffuse heat energy involves a variety of tissues, organs, and organ systems. These systems must

communicate and support each other to satisfy the demands created by greater size and differentiation. Each organism, whether simple or complex, is dependent upon the unique properties of water to metabolize, survive, and reproduce. So intimate is the relationship between water and the structure and function of living organisms that the phenomenon of life as found on this planet is inconceivable in the absence of water. There is no concrete evidence of life anywhere else at this time. However, there is good evidence that water is abundant in the universe. Therefore, it is likely that if living organisms are ever found elsewhere, they will share many characteristics with those found here on earth, because of the inextricable relationship between life and water.

### SAFETY OF WATER

The understanding that some water caused disease while other water sources did not has long prompted human civilizations to attempt to make water safe to drink. Sanskrit medical lore from around 2000 B.C.E. mentions boiling foul water, exposing it to sunlight, and filtering through charcoal. It is possible that the Asian custom of drinking tea made with boiling water was an early method to make water safe to drink. Cyrus the Great in the sixth century B.C.E. took vessels of boiled water with his troops

## BOTTLED WATER

As news reports of contaminated municipal water supplies proliferate, more and more Americans are purchasing bottled water. Between 1976 and 1997 yearly sales of bottled water skyrocketed from 500,000 gallons to almost 3.5 million gallons. Even though the cost of bottled water is 240 to 10,000 times more per gallon than that of tap water, the industry continues to grow at a rate of 8 to 10 percent per year. Many people buy bottled water with the assumption that it is safer than regular tap water.

Bottled water is considered a food and as such is regulated by the FDA under the Code of Federal Regulations Title 21, Part 165, Section 110. FDA considers carbonated water and seltzer water to be soft drinks, and thus regulates them as such. FDA regulations only apply to products that are sold in interstate commerce. Therefore, FDA does not regulate bottled waters that are packaged and sold within the same state, an estimated 60 to 70 percent of all bottled water sold in the United States. States regulate bottled water to varying degrees. One-fourth of bottled water is actually bottled tap water, which may or may not be further treated. EPA regulates tap water.

In its 1999 report, *Bottled Water: Pure Drink or Pure Hype?*, the Natural Resources Defense Council (NRDC) found that, while most of the bottled waters they tested were of high quality and safe, some brands were contaminated. The NRDC also believes that EPA regulations governing tap water are more stringent than the FDA regulations for bottled water. The NRDC concluded that bottled water is not always safer than tap water.

FDA has also established current good manufacturing practice (CGMP) regulations for processing and bottling drinking water, which apply to all waters sealed in bottles, packages, or other containers. Under the CGMP regulations for bottled water, the water to be bottled must be from an approved source and must be processed, packaged, transported, and stored under safe and sanitary conditions. The International Bottled Water Association has also produced a voluntary model code for use by its members.

when they traveled to do battle. Residents of Alexandria, Egypt in 50 B.C.E. drank Nile River water brought to the city through a series of underground aqueducts to cisterns where it was clarified by sedimentation. Other parts of the Egyptian empire used single, double, and even triple filtration to purify water. Sextus Julius Frontinus, water commissioner of Rome in 97 C.E., wrote the first detailed description of a public water system in his *Two Books on the Water Supply of the City of Rome*. While these early water engineers had no understanding of bacteria and were probably treating water to decrease its cloudiness and improve its looks and taste, they nevertheless developed the earliest water treatment systems.

In one of the earliest cases to link a specific disease to the water supply, Dr. John Snow demonstrated in 1855 how cholera spread through water pumps during a large outbreak of the disease in London. He noticed that people who obtained their water from a particular well were more likely to become ill than those drawing their water from another well. He persuaded city officials to remove the pump handle from that particular well, forcing inhabitants to draw water from another well, and the number of cholera cases dropped immediately.

### The U.S. Water Supply

In 1799 Philadelphia became the first U.S. city with a public water system that pumped water from a surface source and distributed it through a series of pipes to residents. By 1900 there were more than 3,000 public water systems in the United States. Rather than guaranteeing a safe water supply, some of those systems actually contributed to major disease outbreaks in the early 1900s. If the water supplies were contaminated, the pumped and widely distributed water provided a means for spreading bacterial disease throughout communities. Federal regulation of the nation's drinking water began in 1914 when the U.S. Public Health Service (PHS) imposed bacteriological standards for drinking water. These standards were revised in 1925, 1946, and 1962 and were eventually adopted by all fifty states. After World War II, industrialization and the use of fertilizers on crops began to pollute the quality and safety of the nation's water. A 1969 survey showed that only 60 percent of water systems delivered water that met PHS standards. A study in 1972 detected thirty-six chemicals present in already treated water taken from the Mississippi River. This increased awareness of the problems with the water supply led to the passage of federal environmental and health laws dealing with polluted water, hazardous waste, and pesticides.

Current water use in the United States averages about 100 gallons per person per day, more than just about any other country. A very small proportion of this, approximately two gallons, is actually used for drinking and cooking. Drinking water comes from either surface water or groundwater. Surface water includes rivers, lakes, and reservoirs, while groundwater is pumped up

from wells drilled into aquifers, underground geologic formations that contain water. Over half the nation gets its drinking water from groundwater sources.

The more than 170,000 water systems in the United States are either private or public. Private water systems do not draw water from a public water supply and serve

only one or a few homes. Public water systems include community water systems and those at schools, factories, campgrounds, and some restaurants that have their own water supply. Community water systems deliver water to people year-round in their homes. In most community water systems, a network of underground pipes transports water under pressure to smaller pipes that then enter individual homes.

### Hazards to the Water Supply and Treatment Methods

Because water is the universal solvent, many chemicals and other materials easily dissolve in it. Water supplies become contaminated through many different channels—chemicals can migrate from disposal sites; animal wastes and pesticides may be carried to lakes and streams by rainfall runoff; human wastes may be discharged to receiving waters that ultimately flow into water used for drinking. Other sources of contamination include discharge from industry, erosion of natural deposits, corrosion of household plumbing systems, and leaching from septic tanks. Nitrates, inorganic compounds that can enter water supplies from fertilizer runoff and sanitary wastewater discharges, are especially harmful to young children. Naturally occurring contaminants are also found in drinking water. For example, the radioactive gas radon-222 occurs in certain types of rock and can seep into groundwater. It would be impossible to remove all contaminants from our water supply. It would also be unnecessary since at very low levels many contaminants are generally not harmful.

Most outbreaks of waterborne disease are due to contamination by bacteria and viruses, mostly from human or animal waste. Two pathogens commonly associated with drinking water are *Cryptosporidium parvum* and *Giardia lamblia*. Both are protozoa that cause gastrointestinal illness and have cysts that are difficult to destroy. *Cryptosporidium* in particular may pass through water treatment filtration and disinfection processes in sufficient numbers to cause health problems. *Cryptosporidium* was first documented as posing a threat of infection to humans in 1976. A 1993 outbreak of cryptosporidiosis in Milwaukee, Wisconsin, is the largest outbreak of waterborne disease to date in the United States. Milwaukee's water supply, which comes from Lake Michigan, is treated by filtration and disinfection. Due to an unusual combination of circumstances during a period of heavy rainfall and runoff, water treatment was ineffective. An estimated 403,000 persons were affected by the disease, 4,400 were hospitalized, and at least 50 died. The original source of contamination is still unknown. Although *Cryptosporidium* had previously been found in surface water, it was not expected to appear in treated water from a municipal water supply that met state and federal standards for acceptable water quality. Increased awareness of the parasite has led to increased testing for it, and, not surprisingly, increased prevalence has been discovered. In

addition to drinking-water outbreaks, *Cryptosporidium* is associated with swimming pools and amusement park wave pools. This is particularly important as *Cryptosporidium* is highly resistant to chlorine and other chemical disinfectants. This is a new parasite showing up in new environments with new resistance capabilities.

Runoff from farms is another source of hazards to the nation's drinking water. In 1994 the Environmental Working Group released *Tap Water Blues*, a report in which the group identified over ten million individuals who had been exposed to five herbicides at levels above the Environmental Protection Agency's (EPA) negligible cancer risk standard of one additional case per million individuals. A second report in 1995, *Weed Killers by the Glass*, analyzed herbicides in the tap water of twenty-nine Midwestern cities. Again, their results show that Americans are exposed to harmful pesticides in their drinking water at levels far above federal health standards.

The Centers for Disease Control (CDC), the EPA, and the Council of State and Territorial Epidemiologists collaborate to maintain a surveillance system that collects data on waterborne disease outbreaks (WBDOs) from drinking and recreational water. This program seeks to determine what pathogens in the water supply cause illness, how many people become ill, and how and why outbreaks occur. The data are submitted on a voluntary basis and most likely underestimate the true incidence of WBDOs. More WBDOs occur in the summer months, and the cause is often unidentified. WBDO outbreaks peaked between 1979 and 1983 and have been declining ever since. This decrease could be due to improved implementation of water treatment regulations, increased efforts by many water utilities to produce drinking water substantially better than EPA standards require, and efforts by public-health officials to improve drinking-water quality. Of the waterborne disease outbreaks reported to the CDC from 1974 to 1996, about 12 percent were caused by bacterial agents, 33 percent by parasites, 5 percent by viruses, 18 percent by chemical contaminants, and 31 percent by unidentified agents.

During 1997 and 1998 there were seventeen outbreaks in drinking water, resulting in 2,038 people becoming ill. Six (35.3 percent) of the illnesses were caused by parasites (4 by *Giardia*, 2 by *Cryptosporidium*); four (23.5 percent) by bacteria (three by *E. coli* O157:H7 and one by *Shigella sonnei*); five (29.4 percent) were of unidentified origin; and two (11.8 percent) were attributed to chemical poisoning. Both chemical poisonings were from copper. Eight (47.1 percent) of the seventeen WBDOs were associated with community water systems. Of these eight, three were caused by problems at water treatment plants, three were the result of problems in the water distribution systems and plumbing of individual facilities, and two were associated with contaminated, untreated groundwater. Five (29.4 percent) of the seventeen WBDOs were associated with noncommunity water systems; all five were from groundwater (i.e., a well or spring) sys-

tems. The four outbreaks (23.5 percent) associated with individual water systems were also from groundwater.

Also during 1997 and 1998, eighteen outbreaks associated with recreational water caused 2,138 people to become ill. Nine (50 percent) were caused by the parasite *Cryptosporidium*. The other outbreaks were due to *E. coli* O157:H7 (three outbreaks or about 16.7 percent), *Shigella sonnei* (one outbreak or 5.6 percent), Norwalk-like viruses (two outbreaks or 11.1 percent), and unknown causes (three outbreaks or 16.7 percent). Slightly over half (55.6 percent) occurred in treated water—pools, hot tubs, or fountains; the others occurred in fresh-water lakes, rivers, or hot springs.

Depending on the conditions and types of contaminants likely to be found in a particular water source, most water suppliers use a combination of two or more treatment processes. Major water treatment processes are:

**Flocculation/sedimentation.** Flocculation is the process of getting small particles to combine into heavier particles called floc. The heavier particles can then be removed by letting them settle out as sediment. Once settled, the particles combine to form a sludge that is later removed.

**Filtration.** Filtration removes particles from water by passing the water through a permeable fabric or porous bed of materials. Groundwater is naturally filtered as it flows through porous layers of soil. Some filtration processes can remove very small particles, including microorganisms.

**Ion exchange.** Ion exchange processes remove inorganic constituents such as arsenic, chromium, excess fluoride, nitrates, radium, and uranium if they cannot be removed adequately by filtration or sedimentation. Electric current is used to attract negative and/or positive ions to one side of a treatment chamber for removal.

**Adsorption.** Adsorption involves making organic contaminants that cause undesirable color, taste, or odor stick to the surface of granular or powdered activated carbon.

**Disinfection.** Disinfection refers to killing harmful microorganisms. The three most commonly used methods of disinfection are chlorination, ozonation, and ultraviolet treatment. Chlorination is the method most often used in the United States while ozonation is very common in Europe.

**Chlorination.** Chlorine kills bacteria by forming hypochlorous acid, which attacks the respiratory, transport, and nucleic acid activity of bacteria. Most bacteria are very susceptible to chlorine while viruses are less so. Cysts from *Giardia lamblia* are very resistant to chlorine, and *Cryptosporidium* cannot be readily killed by chlo-

ration. Of concern with this method of disinfection are the by-products (DBPs), particularly trihalomethanes (THMs), formed when chlorine reacts with organic matter that is in the water. Long-term exposure to some DBPs may increase the risk of cancer or have other adverse health effects. THMs are cancer group B carcinogens, which means they have been shown to cause cancer in laboratory animals. EPA regulations limit the amount of these by-products allowed in drinking water.

**Ozonation.** Ozone is created by passing air through an electric current. The ozone gas is then dissolved in water, where it acts as an oxidant to destroy microorganisms. The ozone is removed before the water is used. As there is no residual antimicrobial effect, it is still necessary to chlorinate the water after ozone treatment. Ozone has received increased attention because it appears to be the only disinfectant that is effective against *Cryptosporidium*.

**Ultraviolet light.** Ultraviolet light (UV) does not actually kill bacteria. Instead, it effectively sterilizes them, making it impossible for them to reproduce. The use of ultraviolet light is only practical for small water systems due to the need for the microorganisms to be close to the radiation source. UV does not inactivate *Giardia* or *Cryptosporidium* cysts.

With so many different bacteria that can cause illness, it is not possible to test the water supply for each of them separately. Instead, indicator organisms are used. Coliform bacteria are the most popular indicator organisms for drinking water as they are easily detected in water. Coliforms are a group of bacteria common in the environment and in the digestive tracts of humans and animals. While these organisms are themselves harmless, their presence indicates possible contamination with human and/or animal waste. The effectiveness of disinfection is judged by analyzing water supplies for total coliform bacteria. Presence of coliform bacteria is not acceptable in public water supplies and is a sign that disinfection is required.

## Regulation

Local governments, public water systems, the states, and the EPA work together to ensure that all public water supplies are safe. Local governments have a direct interest in protecting the quality of their drinking-water source, be it groundwater or surface water. Part of the governments' job in protecting the water supply is to oversee land uses that can affect the quality of untreated source water. State public health and environmental agencies have the primary responsibility for ensuring that federal drinking-water quality standards, or more stringent ones required by the state, are met by each public

water supplier. Municipal water systems test their own water systems for residues but do not regulate or test private wells. For households on private wells, state and local health departments usually have some standards for the drinking water, but it is generally up to the homeowner to maintain the quality of the drinking water.

An increased awareness of the vulnerability of the nation's water supply led to the passage of the 1974 Safe Drinking Water Act (SDWA). Prior to 1974 each state ran its own drinking-water program and set local standards. As a result, drinking-water protection standards differed from state to state. The act authorized the EPA to establish national enforceable health standards for contaminants in drinking water, encouraged federal-state partnerships in protecting the nation's water supply, and required notification to alert customers to water-system violations. In 1986 the act was strengthened through the Surface Water Treatment Rule, which requires public water systems to filter and disinfect all surface-water supplies. In 1996 amendments to the act extended the protection of drinking water from source to tap. Provisions in the 1996 amendment include the following:

- Consumers must receive more information about the quality of their drinking-water supplies. Water suppliers must notify customers within twenty-four hours of violations of EPA standards “that have the potential to have serious adverse effects on human health as a result of short-term exposure.” If such a violation occurs, the system must announce it through the media and provide information about potential adverse effects on human health, steps taken to correct the violation, and the need to use alternative water supplies (such as boiled or bottled water) until the problem is corrected. When microorganisms such as those that indicate fecal contamination are found in drinking water, water suppliers may be required to issue “boil water notices.” At least 725 communities, including New York City and the District of Columbia, have issued boil water notices affecting over 10 million people.
- The SDWA amendments also require public water systems to prepare Consumer Confidence Reports. These are to inform consumers about the source of their water supply, contaminant levels detected in their water, and the health effects of contaminant levels that are above the established safety limit. Beginning in 1999, systems are to prepare and distribute the reports annually.
- Under the new amendments, each state must develop a program to identify potential contamination threats and determine the susceptibility of drinking-water sources to activities that may harm the source water.
- The 1996 SDWA Amendments provides up to \$9.6 billion over six years to improve drinking-water in-

TABLE 1

Sample monitoring schedule

Contaminant	Minimum monitoring frequency
<b>Acute Contaminants</b>	
Bacteria	Monthly or quarterly, depending on system size and type
Protozoa and Viruses	Continuous monitoring for turbidity, monthly for total coliforms, as indicators
Nitrate	Annually
<b>Chronic Contaminants</b>	
Volatile Organics (e.g., benzene)	Groundwater systems, annually for two consecutive years; surface water systems, annually
Synthetic Organics (e.g. pesticides)	Larger systems, twice in three years; smaller systems, once in three years
Inorganics/Metals	Groundwater systems, once every three years; surface water systems, annually
Lead and Copper	Annually
Radio nuclides	Once every four years

General requirements may differ slightly based on the size or type of the drinking-water system.

SOURCE: Environmental Protection Agency (EPA). July 1997. *Water on Tap: A Consumer's Guide to the Nation's Drinking Water*. Washington, D.C.: Environmental Protection Agency, Office of Water, 1997. Available at <http://www.epa.gov/OGWDW/wot/ontap.html>

frastructure. Water systems can apply for low- and no-interest loans to upgrade their facilities and ensure compliance with drinking-water standards. Other sources of funding are also available to water systems through the U.S. Department of Agriculture's Rural Utility Service (RUS). As part of the Water 2000 initiative, which is aimed at providing clean, safe, and affordable drinking water to all rural homes, RUS administers a water and wastewater loan and grant program. Under the RUS programs, rural areas and small cities and towns can receive loans or grants to restore a deteriorating water supply, upgrade a water or wastewater facility, or develop new systems.

The EPA Office of Water sets standards for pesticides and other chemicals in drinking water and issues Maximum Contaminant Levels (MCLs), which limit the amount of each substance that can be present in drinking water, for more than eighty contaminants. Scientists use a process called risk assessment to set drinking-water quality standards. When assessing the cancer and non-cancer risks from exposure to a chemical in drinking water, the first step is to measure how much of the chemical could be in the water. Next, scientists estimate how much of the chemical the average person is likely to drink. This amount is called the exposure. In developing drinking-water standards, the EPA assumes that the average adult drinks two liters of water each day throughout a

seventy-year life span. MCLs are set at levels that will limit an individual's risk of cancer from that contaminant to between one in 10,000 and one in 1,000,000 over a lifetime. For non-cancer effects, risk assessment provides an estimate of an exposure level below which no adverse effects are expected to occur. The EPA also takes into account the ability of various technologies to remove the contaminant, their effectiveness, and the cost of treatment.

To comply with MCLs, public water systems may use any state-approved treatment. According to 1996 statistics, 7 percent of community water systems, or 4,151 systems, reported one or more MCL violations, and less than 2 percent (681 systems) reported violations of treatment technique standards. The table shows the major groups of contaminants and the minimum frequency with which water systems must test for them.

Finally, Healthy People 2010, a national health-promotion and disease-prevention initiative, has two goals for water quality:

1. Increase the proportion of persons served by community water systems who receive a supply of drinking water that meets the regulations of the Safe Drinking Water Act. The current baseline is 73 percent; 2010 goals are to increase that to 95 percent.
2. Reduce waterborne disease outbreaks from drinking water among persons served by community water systems. Currently an estimated six outbreaks per year originate from community water systems. The goal is to decrease that to two outbreaks per year.

**WEDDING CAKE.** Wedding cakes are elaborate constructions, each standing for a particular marriage and each used in the wedding that establishes it. The link between cake and wedding, the distinctiveness of its form, its derived uses, and the meanings attached to it have all been most complexly and influentially developed in the English-speaking world. A classic form was commercially established in Britain and the United States in the early years of the twentieth century. An exceptionally large, rich fruit cake, as much as twelve inches in diameter and twenty pounds in weight, was used as a base for pillars supporting a similar but smaller cake. A third, still smaller cake layer was mounted on another set of pillars above that. The three tiers were each covered with hard white “royal” icing, which also was used for a characteristically formal decoration of piped icing. The whole was crowned with flowers, natural or in a variety of artificial materials, or a limited range of other appropriate ornamentation that might also adorn the sides. This form traveled widely in the course of the twentieth century and was modified locally in relation to changing tastes and the development of new decorative potentials and uses. Though the classic form was especially tenacious in Britain, the knowledge of alternatives, contributed by different European traditions, spread with increasing rapidity. The significance of the cake shifted from representing marriage as a fixed reality into which each couple entered to representing the individuality and even originality of the couple celebrating.

#### Historic Sources

The classic form had three sources, the use of loaves at Christian marriage rites, the appearance of “subtleties” and later sugar sculpture in medieval and Renaissance banquets in Europe, and the development of the English form of the substance “cake,” mainly in the seventeenth century. Decorated loaves had been carried to the church in pre-Reformation wedding processions to be blessed

The royal wedding cake created at Windsor Castle in 1871 for the marriage of Princess Louise and the Marquis de Lorne. This cake, which stood over five feet tall, is crowned with a figure of a vestal virgin. It was one of the first wedding cakes to introduce the idea of tiers and height and became a prototype of the many-tiered wedding cakes of today. Wood engraving from the *Illustrated London News*, 1 April 1871. ROUGHWOOD COLLECTION.

and then returned to be eaten at a popular celebration following. Possibly earlier, and certainly later, there were baked but unleavened items more like Scottish oatcakes and shortbread: the “infare cake” is well known in the literature. These cakes were to be broken over the bride’s head and/or eaten at the marriage feast. How widespread such practices were is not known, but these were among the variety of things to which the term “bride cake” has been applied over the centuries.

A clearer continuity is represented by the rich fruitcake developed in England by a process of enriching breads with sugar, spices, and dried fruits. The transformation was achieved by the mid-seventeenth century, providing a luxury that might be baked for wedding celebrations in the homes of the wealthy. Icing for cakes followed, and in 1769 a Manchester confectioner, Elizabeth Raffald, included the recipe for an iced “bride cake” in her cookery book, *The Experienced English Housekeeper*. This recipe was for a distinctive rich fruitcake covered with two layers of icing, a naturally pale yellow almond icing encased in a hard outer layer of plain white icing. Over the next century this became the distinguishing formula for British celebration cakes of increasing variety.

The subtleties of medieval Europe were, like modern wedding cakes, display items designed to impress and amaze as well as to be at least marginally consumable as food. The tradition culminated in the production of sugar sculpture for some of the greatest court festivities of the Renaissance period. They had no specific link with wedding feasts, but when revived in the enthusiasm for historic forms and styles in the nineteenth century, they acquired it. Led by the British royal establishment, for the weddings of Queen Victoria’s children superstructures of sugar architecture and sculpture were raised on bases of cake, transforming them into tall centerpieces for the tables of wedding banquets. The decoration was characteristically white, and made symbolic references to the royal alliance. By the end of the century their example had stimulated leading baker-confectioners and enthusiasts for the art of piping into commercial developments leading directly to the three-tier classic. Typically only wealthy customers could initially afford the product, but in the course of the following half-century it became the standard for all.

### Meanings and Uses

The classic form of the cake was impersonal, excluding written inscriptions or any direct reference to the personal tastes or interests of the couple marrying. Decorative motifs were confined to the most genteel of references to love and constancy. White, and if not white, silver, predominated. The cake was indeed a prime component of the white wedding. This, though it has not been well studied, appears to have developed at a period when public attention was increasingly drawn to sex and when, among the respectable classes, embarrassment on this score in the context of marrying was strong. The formality of the white wedding and of the style of the classic cake with it was, it has been argued, a strategy for diverting attention from the sexual implications of marrying to the decorous purity of the bride.

The cake acquired a particular relationship with the bride in two ways. It was heir to popular traditions that centered weddings on the transition the bride was making. As noted above, this sometimes involved breaking baked items over the heads of brides. Unmarried young

Traditional wedding cakes baked in the shape of floral wreaths. Rethymnon, Crete, 1996. Most very old types of wedding cakes like these were little more than enriched bread, although elaborately ornamented. © GAIL MOONEY/CORBIS.

people often obtained fragments to dream on to discover their own life partners. The second link arose when cakes spread more widely in the social scale in the mid-nineteenth century, from the aristocratic wedding banquet to the modest domestic wedding breakfast. In this new context, the bride in her new married status was called on to cut the cake for her guests. Cut pieces could then take on the old use for divination. In the twentieth century cake cutting became one of the major popular rites of marrying, but it developed into a joint action by the new husband and wife together. In Japan this theme was developed to the exclusion of edibility. The joint insertion of a knife into a slot in an enormous wax cake provided a striking photo opportunity as part of a complex sequence developed in commercial wedding halls. In the United States a mutual feeding of cake by bride and groom extended the symbolic use in another direction.

More esoteric meanings have at times been discovered for the wedding cake and its uses. The complexity of the classic form and its apparently traditional nature often encouraged speculation on the contrast between the dark interior and the whiteness of the exterior and on the meaningfulness of ingredients and their flavors. The almond, appearing in one layer of icing as well as in the mixture inside, attracted particular attention. Most spectacular has been the identification of the white, tiered cake with the bride in her wedding costume and the joint cutting of the cake as a symbolic consummation of the marriage. As forms have diversified, the scope for such symbolic interpreting has declined.

**WEDDINGS.** Weddings are a universal life cycle event where rituals and ceremony display a group's interest, whether conspicuously or obscurely, in economics, organizational balance, power, and social forms. Nuptials allow families and couples to establish a new status in society; this is especially true for the bride as she is now an adult woman, belonging to her husband's family and responsible for perpetuating his (and now her) lineage. Upon marrying, the groom also gains a new status of respectful adulthood, a full member of society.

One major role of food in this rite of passage is the show of opulence and social status. For example, the

My small-leaf basil  
and my marjoram  
it is you who will separate me  
from my mother  
Come to the window  
girl, the one with the glass pane  
to see your face  
[which is as white as] flour  
The stairs you ascend  
[I wished] I ascended too  
and at every step  
to give you sweet kisses

*Traditional song sung by village musicians reserved for the women as part of the nuptial festivities (Argyrou, Tradition and Modernity in the Mediterranean, p. 69).*

English nobility of the late Middle Ages had their own ideas regarding the proper wedding feast: boar and lamb were served as a first course, followed by venison in broth and antelope served with a spiced, sweet pudding containing rice flour. The third course contained fish and a baked meat and began with lozenge and almond cream in syrup; cheese, hot bread, a sweet, and other dishes were the fourth course.

### Weddings in Greece

As Vassos Argyrou writes in *Tradition and Modernity in the Mediterranean* (pp. 60–110), weddings in Cypriot and other small villages of Greece were five- to six-day affairs in the 1930s. The nuptial rites customarily began on a Friday or Saturday with the preparation of the *resi*, a dish particular to the Limassol and Paphos areas. The communal preparation of the *resi* is the first of many fertility rituals; here the crushed wheat, pork, chicken, and other meats represent the abundance and fertility of the land upon which the couple would make their home. First, a group of village women cleaned the wheat by removing inedible portions and stones. Then, having placed the cleaned wheat in large wooden vessels, *skafes*, and covered these bowls with red shawls, the women, led by musicians, proceeded to the village fountain. After washing the wheat seven times in a step called *efta plimmata*, the wheat was returned to the bride's house in the same processional fashion, where it was pounded until crushed by using a *faouta*, a rectangular paddle with rounded edges. While the *resi* would not be served until the Sunday feast, the lengthy preparation process customarily started on Friday, and the dish was cooked on Saturday.

After the church ceremony, *stefanoman*, on Sunday, the couple and their guests returned to the newlyweds' home to perform one of the many rituals of that day. In

response to good wishes from guests, the couple sprinkled the guests' hands with rosewater. Afterwards, men were served a glass of homemade wine, while the women were given a dish of fruit preserved in syrup, *gbliko*. An elaborate feast followed, attended by many people of the village. They dined on the traditional *resi*, potatoes *yakhni* (cooked in tomato sauce), *kolokasi* (a root vegetable similar to a sweet potato), salads, beets, and meats. The traditional beverage selection was limited to homemade wine and *zivania* (grappa).

On Monday, food such as *kanishia*, potatoes, olive oil, cheese, pasta, chicken, and wine was brought by people of the community to the couple's home. These gifts would unofficially set the guest list for the dinner served later that evening; in addition, they served as a hospitality gift to the couple's families with implications of future reciprocity.

The final rituals of the week were to *kopsimon ton makarounion* (the cutting of the pasta) and to *sinaman ton ornithon* (the collection of the chickens). These events took place on Tuesday and were attended by those who could not participate in Sunday or Monday's festivities. Accompanied by live musicians at the couple's home, the women rolled small pieces of dough between their palms, producing long, thin pieces which they then cut into small pieces. The collection of the chickens began after cutting the pasta, where young men gathered chickens from various village households (usually homes of invited guests). Also part of a musical procession, the youths brought the chickens home to be slaughtered and prepared with the pasta for the evening meal.

Greek weddings in the 1930s were not a small family affair; weddings were public celebrations, as almost all community members were considered friends and members of the family. Fathers of the bride and groom also felt their family name required a worthy nuptial celebration; thus, in Paphos, weeks before any actual celebrations, the two families distributed a special bread called *yiristarka* as an invitation.

### Weddings in India

In an 1899 article titled "The Hill Tribes of the Central Indian Hills," William Crooke describes the Hindu-based wedding customs of several tribes. These customs emphasize the role of food in carrying out rites promising fertility, happiness, and abundance. An initial marital rite takes place when the parents of the newly betrothed couple drink together out of vessels made from the leaves of a holy tree. For brides of the Majhwâr tribe, entry into the couple's new home is forbidden until she and her husband eat rice boiled in milk. A young Dhobi male will not consume boiled rice before his wedding feast so as to preserve the sacred meaning of this ritual. Some Bengali tribes practiced a custom where blood was drawn from the husband's finger and mixed with betel and eaten by the bride. Rice also enters the nuptial customs as five mounds of rice are placed on a stone and the

bride is made to knock them down with her foot symbolizing her departure from her natal family and her entry into the family of her husband.

Grains continue to represent fertility across the world's cultures as special wheaten cakes are prepared for the newlyweds to walk on; women throw betel and barley over the groom as he enters his new home; and the bride's brother pours wheat, rice, or barley over the bride as she turns around.

### Boiotian Weddings

Ancient Boiotian weddings were secondarily presented and analyzed in the nuptial iconography of several vases found in the Kanapitsa cemetery of Thebes. Researchers believe the fertility ritual of *katachysmata*, where the bride and groom are showered with cakes, figs, apples, nuts, and other fruits, is depicted, as well as the practice of the bride consuming a quince, apple, or other fruit to signify her public transition into her new role as a married woman.

In Greek Orthodox wedding ceremonies, the bride and groom sip wine from the same cup as a symbol of the shared cheer and unpleasantness they will experience in their life together.

### Chimbu Weddings

The Chimbu of the New Guinea highlands live in a world where transactions define all relationships and interpersonal interactions. These dynamic operations—gifts, tolls, assistance—carry many implicit meanings which test loyalty and create intergroup balance. Chimbu weddings provide opportunities for groups to participate in transactional gift-giving and feasting; sweet potatoes are given or exchanged at weddings, as are bean roots and nuts when available. Marriages often occur at the height of a pig ceremony where numerous pigs are sacrificed, *bulga kande*, and cooked at a ceremonial ground; also at this time, male dancers enact a fertility rite, blessing the women, pigs, and sweet potato vines. Along with the gift of vegetable produce, the widely traditional cooked pig meat is distributed among those who cooked it and individual kinsmen.

### Nias Weddings

The wedding feasts of the Nias people—Nias is the largest chain of islands off the west coast of Sumatra—also include a large amount of pork. Preparation for the traditional feast at the bride's house begins when the groom's party begins a procession over the hills involving gongs and drums and a small herd of about six pigs. Upon arrival at the bride's house, the men are served betel. Many hours and ritual transactions later, two pigs (*barwi buku*, law pig, and *barwi vangovalu*, wedding pig) are slaughtered by an elder or member of the bride's party to commence the main attraction of the feast. Provided by the groom, the raw pig is ceremoniously and carefully butchered into portions; the lower jaw, the most prized

The state wedding feast of Peter I of Russia is detailed in this 1712 engraving by Alexei Zubkov. © THE STATE RUSSIAN MUSEUM/CORBIS.

portion, is divided into four. The bride's father and his close relatives and elders of the bride receive a portion running the whole length of the pig. A small quantity is cooked for the bride's relatives, and the remaining raw portions are given to the chief, wife-givers, and butchers.

The host reciprocates the gift of the wedding pig with another larger pig, *barwi daravatö*. Once again the pig is split among the guests; the groom takes one leg and a hind-part (about one-quarter of the animal) home to his village, the groom's speaker receives one back section, and the host is entitled to a leg and the lower jawbone as a token of the evening. The remaining parts are cooked and served to all other guests. The groom and his family members receive the lower jaw, belly, and heart served on a large mound of rice, while he and his bride eat from the same plate. Status determines the size and type of portion; thus, only the elders of each group are entrusted with the duty of distributing the meat.

The betrothal of a Nias couple is solidified with *feamanu*, the eating of the chicken. Provided that specific omens which can break the contract are not encountered, the couple will eat the cooked chicken as their first meal together, and a small pig will accompany the meal. Raw and cooked portions, especially the lower jaw, are cut and given to the groom's father.

### Weddings in China

The marriage customs observed in 1938 of the Chinese in the town then known as I Chang, located on the north bank of the Yangtse River, required preparations to begin at least one year in advance. During this time, pigs must be fattened, rice and other foods accumulated, and goats and chickens prepared. About one week before the wedding ceremony, final preparations for the wedding

A Hungarian immigrant wedding held near Wilkes-Barre, Pennsylvania, about 1906. The bride and groom are standing behind the bride's parents on the right. ROUGHWOOD COLLECTION.

feast began. The feast, which lasted four hours, included nine courses; the first course was cuttlefish or sea slugs and wine; the roundness of the meatballs of the fifth course represented a coming together of the groom greeting his guests; the ninth course also included fish, *yü*, which also means surplus, ending the meal with an omen to abundance in the couple's future.

In *The Wedding Day in All Ages and Countries* by Edward J. Wood published in 1869, Wood writes on the various wedding rituals throughout the world. In Athenian tradition, sweetmeats, symbolic of abundance, were gingerly thrown upon the couple as they walked into a house for the nuptial feast. Later on, a quince was shared by the pair in hopes that their marriage would be agreeable. A man in Algiers placed fish at his new wife's feet for good luck. Past Chinese tradition called for a quilt, held by her relatives, to be placed in front of the bridal chair and as the bride sat there, four bread cakes were thrown into the air so that they would land on the quilt; this ritual also represents good luck.

Later in the course of this days-long elaborate marriage ritual, tea and poached eggs with sugar were served three times to the guests. The groom and his party only feign partaking of these refreshments since actual consumption would violate social etiquette. Numerous tea ceremonies take place, often followed by a serving of tobacco.

While preparing the nuptial bed, two women selected by the groom's family place cakes, dried *lungan* nuts, red-stained peanuts, and ginko nuts in the bed. Young girls search for these goods and eat them in hopes of future fertility. In a ceremony to finalize the marriage, the bride and groom are each given a glass of wine; they drink half the contents, exchange the cups, and finish consuming the rest of the wine; the same ritual is done with pieces of candy after the wine.

To ensure that as a wife the bride will be thorough in completion of her duties, she places a pre-prepared fish in the stove with the head pointing toward the front of the stove, and the tail in the back. This ritual, *yu tou yu wei*, says that she will be thoroughly dutiful. In addition, a dish of steamed vegetables mixed with rice flour, *chêng tsai*, is prepared by the bride, symbolizing abundance.

### Contemporary Hindu Rituals

Contemporary Hindu wedding rituals also involve food at almost every stage in the ceremony. In a prenuptial rite at the bride's and groom's homes, male and female guests heat the couple's bodies to ready them for sexual

intercourse by rubbing them with turmeric. In another preliminary ritual, the groom's party is served a light *pakka* (fried) meal at the bride's house, then the bride sits behind a mound of rice, and the groom's father places coconuts and sweets (believed to be auspicious) and money in her lap.

During the main nuptial ritual, the priest pours rice into a small tray held in the bride's right hand. The groom places his arm around her shoulders and knocks the rice onto the ground seven times. After the ceremony is completed, *Mubajayana* takes place. During this rite, the bride fills a metal tin with uncooked rice and holds it on the ground for the new husband to kick over seven times. The disturbance of the raw grain by the male in these two practices places him in an active role for reproduction.

Also during *Mubajayana*, the wife cooks a mixture of rice and pulse, *khichri*, for the groom and his younger brothers. When the husband is full from his portions, he hands the leftovers to her for her to eat. This act embodies the belief that the leftovers of a superior confer a blessing on the subordinate who consumes them.

## WHEAT.

*This entry includes two subentries:*  
The Natural History of Wheat  
Wheat as a Food

### THE NATURAL HISTORY OF WHEAT

Wheat's beginnings can be traced to a clan of wild grasses called *Triticeae*, the seeds of which had a flavor that was pleasing to primitive people. *Triticeae* included wheat,

barley, rye, their wild relatives, and a number of important wild grasses. The Fertile Crescent, at the core of western Asia and northern Africa, is the center of origin and early diversification of this clan. Wild einkorn and emmer, which have been known for roughly 75,000 years, are credited as wheat's earliest ancestors. The ripple effect of these grains has been immense, since wheat is the most widely produced and consumed cereal grain in the world.

Through the archeological evidence left by nomadic humans in west Asia, researchers have learned that humans adapted from hunting animals to also gathering seeds for food. Periods of glaciers no doubt inspired this move by reducing available game. The early gatherers were also the first millers and selected grains that could be most easily released from their glumes or husks and prepared. People parched, simmered, and ground these grains and prepared flat cakes. Thus, using grains as food changed the way early ancestors lived their daily lives, in addition to providing basic sustenance. The evolution of agriculture and cultivating seeds for harvest (which occurred about 9,000 to 10,000 years ago) changed not only the available food supply but how people moved about. Human beings' ability to process (mill), store, cultivate, and trade grain marked the beginnings of civilization.

### Beyond Grass: The Early Use of Wheat

As mentioned earlier, early wheat was part of a clan called *Triticeae* and is classified under the Old World genus *Triticum*. Wheat's early relatives had seed heads that were brittle and easily broken apart and the hulls clung to the grains. This made the seeds better for re-seeding but also difficult to thresh.

Primitive women who were responsible for the tasks of gathering, threshing, grinding, and cooking would have selected heads with the largest grains and sought out those that were easiest to thresh or separate from the hulls. Some early wheat species grew as tall as six feet, but modern varieties average two to three feet in height. Domestic wheat is selected and bred for strong seed heads that do not shatter easily and that release the glumes or hulls so the kernels are bare.

Einkorn (*Triticum monococcum*) is considered to have been the first wheat gathered and cultivated. Its centers of early distribution were Armenia, Georgia (in the former Soviet Union), and Turkey, where it is still grown and eaten. Impressions of einkorn are found in Neolithic pottery as far north as Great Britain and Ireland, but there are no prehistoric records of it in India, China, or Africa.

All plants are identified by their chromosomes. Every variety of wheat grown today has arisen from wild, fourteen-chromosome wheat, undoubtedly einkorn. Einkorn and fourteen-chromosome wild grass crosses created twenty-eight-chromosome (tetraploid) wheats. Only one twenty-eight-chromosome species can be found in nature: wild emmer (*T. dicoccoides*). It grows in

## EARLY BEGINNINGS

Archeologists look for certain evidences of early agricultural society. These include tools for pounding or grinding grain; pottery or means of quantity grain storage; remains of a permanent settlement; tools for planting, sickles or scythes for harvest; and related religious symbols. Some of the earliest finds include the following.

**Pre-agriculture** (Early wheat ancestors—wild einkorn and emmer—are gathered and ground.)

- 75,000 years ago—Simple roundish stones one-and-one-quarter-inch thick and four inches across, with flat working surface, such as the Aragnacian combination grinding stones, found in La Combe, France.
- 20,000 years ago—Mortar stones are an improvement, such as a dip to contain the product while grinding/pounding, found in Magdalenia, Vézère valley, France.
- 12,000 years ago—Pounder-rubber for grain and possible sickle-like blade from Azilian culture, found in Mas d'Azil, France; also found in Danish Maglemose period.
- 10,000 years ago—Pounder-rubbers—found in Pinto Basin, Riverside County, Calif., and Oak Grove Natives, Santa Barbara, Calif.

### **Early agricultural period**

- 10,000 years ago (Stone Age)—Einkorn cultivated in southeastern Turkey.
- 9,500 years ago—Clustered mud-brick houses, cultivation tools, saddle stones (found in Abu Hureyra village, northern Syria).
- 8,700 years ago—Swiss cave dwellers provide evidence of eating wheat in flat stone-baked cakes.
- 8,050 years ago—Sickle blades coated with silica patina from grain stems; sandstone milling stones and mortars, baked pottery (Ghar-I-Kamarband or Belt Cave, northern Iran).

- 8,000 years ago—Goat grass (*Aegilops tauschii*) and wheat (*Triticum turgidum*) cross for the rise of bread wheats.
- 7,500 years ago—Pottery is invented.
- 7,000 years ago—Pottery is used in grain storage and cooking; tools—Natufian culture, Palestine and Sialk, northern Iraq; sickle, Fayum, Egypt; einkorn found in Jarmo, northern Iraq.

the region comprising northern Israel, west Jordan, Lebanon, and adjoining southern and southeastern Turkey, western Iran, northern Iraq, and northwestern Syria.

Emmer (*T. dicoccum*), which closely resembles wild emmer, is the oldest and was once the most widely cultivated twenty-eight-chromosome wheat. Well-preserved spikelets of emmer have been found in Fifth Dynasty Egyptian tombs—the bread bakeries from that period in Egypt's history used emmer flour. Remains and impressions are also common in Neolithic sites in continental Europe, Great Britain, and Ireland. Durum wheats that

are grown today for pasta and couscous are derived from emmer wheat crosses.

### **The Emergence of Bread Wheat**

Varieties of wheat that have forty-two chromosomes are the most recently evolved and most used types of wheat. All of these varieties have been cultivated by humans (as opposed to growing wild). They are hybrids of twenty-eight-chromosome wheats and wild fourteen-chromosome wheats or grasses. Early bread wheat was the result of the crossing of goat grass (*Aegilops*

*tauschii*) with *Triticum turgidum*. Modern bread wheat varieties have forty-two chromosomes and evolved from crosses between emmer and goat grass, which is the source of the unique glutenin genes that give bread dough the ability to form gluten. Goat grass grows abundantly in the region stretching from Greece to Afghanistan. Descriptions of the fourteen species of wheat that yield the thousands of wheat varieties grown today are provided here.

### The Diffusion of Wheat

The fact that prehistoric people accomplished selective breeding of wheat is a testament to their powers of observation and curiosity. Through their efforts and, much later, through the development of the laws of heredity by nineteenth-century Moravian monk Gregor Mendel, wheat began to diversify.

Up through the Middle Ages and into the seventeenth century, the varieties of wheat grown in different parts of the world were often “landrace” (native wheat or wheat grown for centuries in a region) varieties. People carefully selected the biggest and best grains at harvest for seeding the next crop. Through trade routes and immigration, new varieties of wheat were sold or shared by people from different regions. If a type of wheat grew well (in other words, if it resisted soil or airborne diseases, insects, and variations in rainfall or climate), people were likely to continue growing it.

As people emigrated to the Americas and Australia, the varieties of wheat grown in their mother countries were the first seed stock cultivated in the new frontiers. If these crops failed, people tried raising other crops or experimented with wheat seed others had from another region.

### Six Wheat Classes

The wheat foods that we enjoy today are all produced from varieties of wheat bred from the first fourteen species. The wheat industry divides the thousands of varieties available today into six wheat classes: hard red winter, hard red spring, soft red winter, durum, hard white, and soft white wheat. Each wheat class has qualities that millers and food processors seek for specific products. Farmers grow varieties from classes that will grow in their location.

Spring wheat classes (hard, soft, and durum) are planted in the spring and harvested in the summer. Winter wheat is planted in the fall, grows several inches, and may even be grazed by livestock before the grain head develops. Winter wheat lies dormant through the winter, continues growing in the spring, and is harvested in the summer months. Sometimes varieties of spring wheat are planted in the fall, as is the practice in some locations in China.

In general, the hard wheat classes (spring and winter) contain higher quantities of the proteins needed to

## DISTINCT SPECIES OF WHEAT

The thousands of wheat varieties grown today rose from crosses in these fourteen species (Mangelsdorf, pp. 2–11).

### Fourteen chromosomes

- *Triticum aegilopoides* (wild einkorn)
- *T. monococcum* (einkorn)

### Twenty-eight chromosomes

- *Triticum dicoccoides* (wild emmer)
- *T. dicoccum* (emmer)
- *T. durum* (macaroni wheat; first appeared first century B.C.E., Greco–Roman period)
- *T. persicum* (Persian wheat; of no great commercial importance today)
- *T. turgidum* (rivet wheat; of no great commercial importance today)
- *T. polonicum* (Polish wheat; of no great commercial importance today)
- *T. timopheevi* (has no common name; grown on only a few thousand acres in western Georgia [in former Soviet Union])

**Forty-two chromosomes** (First three species—true bread wheats—account for about 90 percent of all wheat grown today.)

- *Triticum aestivum* (common wheat)
- *T. sphaerococcum* (shot wheat)
- *T. compactum* (club wheat)
- *T. spelta* (spelt; grown on only a few thousand acres in western Georgia [former Soviet Union]; once the principle wheat of central Europe)
- *T. macha* (macha wheat; grown on only a few thousand acres in western Georgia [former Soviet Union])

produce bread, buns, pasta (durum), pizza crust, and other bread products. Soft wheat contains lower quantities of protein than hard wheat, and it is conducive to producing tender cookies, cakes, pastries, crackers, Asian noodles, and steam breads.

The white wheat classes are desirable because they lack a red gene in the bran that contributes to a darker color and a slightly bitter flavor to the whole grain. Hard and soft varieties of white wheat are grown increasingly in the United States and Australia.

## New Varieties of Wheat

Developing and planting wheat varieties that resist diseases and insects is essential for a secure food supply, human health, and reducing the use of chemical controls. For example, fungal diseases like Karnal bunt, leaf rust, or smut will ruin entire wheat crops. In the Middle Ages European rye hosted a disease called ergot and was the cause of a horrible plague when the rye was mixed with wheat flour in breads. In more recent times, problems with Karnal bunt have rendered large portions of India's wheat harvest useless, and thousands of acres of Minnesota spring wheat were tilled under due to plant-disease damage.

Wheat hybridization occurs naturally and through human assistance. Wheat breeding has been practiced since people first selected the biggest seeds that were easiest to thresh and stored them for planting. In a formal sense, favorable characteristics such as disease resistance, large kernels, short straw, and cold hardiness are selected in two parent wheats, which are then crossed to form a hybrid.

For example, northern wheat hybrids were first made in Ontario, Canada, in 1885. North Dakota followed this trend in 1892. The early spring wheat varieties that were brought to North America had heads that shattered easily, and farmers needed them to ripen faster. Dr. William Saunders, organizer and first director of the Dominion Experimental Farms, produced a Canadian cross between an Indian wheat (Red Calcutta) and a popular Polish spring wheat (Red Fife) that gave rise to Marquis, a hard spring wheat. Marquis was put into production in 1909 and was soon grown over 90 percent of the northern United States and Canadian plains. It helped alleviate food shortages during World War I.

Another source of many new varieties of wheat is Turkey Red, which was hand-picked and carried to Kansas in 1874 by Mennonites from Crimea, Russia. Turkey Red wheat once covered over 90 percent of wheat acreage in the Great Plains. Winter-wheat research at Kansas State University has given rise to new winter wheat varieties and crosses grown all over the world.

Wheat breeders in centers around the world collect, conserve, and utilize wheat plant materials. Japan first began collecting wheat plant material in the early 1900s. Since the 1960s, wheat research centers have been formed (through private and government funding) in wheat regions all over the world.

It takes ten to twelve years of lab and field tests at a cost of around \$500,000 per new variety of wheat before a seed wheat can be released to farmers for production. There are perhaps 100,000 unique varieties of wheat derived from the six classes worldwide. A variety will commonly be grown for about ten years before a new variety may be needed.

Genetically modified (or GM) wheats were not to be released until the early twenty-first century. The primary

benefit of GM wheat technology is the precision it allows in adding desired wheat characteristics located at specific points on wheat's chromosomes. With wheat breeding or hybridization, all the genetic material from both parents is present in the cross. The resulting variety must be grown in order for researchers to see what attributes are included in the cross. Through genetic mapping, specific traits may be added, such as disease resistance to wheat streak mosaic or the addition of nutritive elements. With GM wheat technology, the testing time for new varieties of wheat may be reduced to as little as two years versus the ten to twelve years needed in traditional breeding programs.

Centers for wheat research also preserve early wheat and grass germplasm while new crosses and genetic research are performed. Wheat research is shared for the improvement of agriculture and food-production systems in all countries.

## Wheat Production

Through centuries of seed selection and modern wheat breeding, wheat can be grown in every temperate climate in the world. World wheat production is perennial, that is, wheat is being harvested in some part of the world in every month of the year.

Wheat is seeded anywhere from sea level to elevations of ten thousand feet. A ninety-day growing season is needed for wheat growth, and a period of dry, sunny weather is preferred for the ripening period. Rainfall between ten and thirty inches annually is required, and soils that range from sandy loam to clay are used to grow wheat. The plant averages between two to three feet in height, and some varieties reach five to six feet.

## Advances in Wheat Production

From 7500 B.C.E. to 1840 C.E. there were surprisingly few mechanical advances in the production of wheat. The invention of the iron plowshare, sickles for cutting ripe wheat, and the use of oxen or horses for tilling and threshing are considered the main advances during this time. With their reliance on human and animal labor and without the availability of machines, agricultural practices greatly limited how much wheat was produced. Fields were left fallow (unplanted) for a year to improve their moisture, and animal manure was used to enrich the soil. Many fields were planted to hay in order to feed essential work animals. Eventually soils were exhausted in Europe, Asia, and other regions where grains had been cultivated for thousands of years.

Three major advances were vital in the expansion and development of wheat production and consumption. First, in the early 1800s, the first soil-chemistry studies were performed. European soil chemists Sir Humphry Davy (from England), Albrecht von Thaer (from Prussia), and Justus von Liebig (from Germany) provided farmers with evidence that the soil had been "robbed" or depleted and that fresh sources of specific chemicals were

## PERENNIAL WORLD WHEAT HARVEST

Wheat is harvested somewhere in the world every month. The world's top wheat producers are China, United States, Romania, Czech Republic, Slovakia, Russia, Canada, Germany, and France.

- January: Argentina, Chile, Australia, New Zealand
- February and March: Egypt and India
- April: Egypt, Asia Minor, Mexico
- May: Algeria, Central Asia, China, United States
- June: Turkey, Spain, France, United States, Italy
- July: Romania, Czech Republic, Slovakia, Austria, Russia, Germany, Switzerland, France, England, Denmark, Poland, United States, Canada, Italy
- August: Holland, Belgium, England, Denmark, Poland, United States, Canada
- September: Scotland, Sweden, Norway, Russia
- October: Scotland, Sweden, Norway, Russia
- November: Peru, South Africa
- December: India, Argentina

needed for crops to flourish again. The manure that farmers were using was not enough for healthy crop production. The inorganic minerals the researchers identified as essential were nitrogen, potassium, lime, and phosphoric acid. By 1843, Dawes in England began producing chemical fertilizers for the exhausted soils of Europe.

The second advance surrounding wheat production involved major improvements in milling technology. James Watt invented the steam engine in 1769. Oliver Evans began automating the milling process in 1785, and by 1834 steam-driven steel roller mills had been introduced in Europe. Steel roller mills were capable of milling the harder spring and durum wheats grown in Canada and the United States. By 1870, superior flour production and a new process called middling purification (created by Edmond La Croix) had created growing wheat demands.

A third major advance, convenient to the homesteading of vast expanses of untilled land in North America in 1862, was the mechanization of U.S. agriculture. In 1842, the Pennock brothers launched a mechanical sower called a drill, and the McCormick reaper was rolling out of factories in 1861. The invention of steam-driven threshing and self-binders meant that, by 1940, producing a bushel of wheat took only sixteen minutes, whereas in 1850 manual labor produced a bushel in four and a half hours. This meant there was no longer a risk of losing crops that were waiting to be harvested by hand. With machines, more ground could be seeded to wheat

instead of animal feed as long as there was adequate rainfall. Delivery of wheat was greatly improved by the advent of cross-continental railroad service. Between 1866 and 1900 U.S. wheat production increased from 175 million bushels to 655 million bushels. Exporting wheat became a new trade opportunity.

## Challenges in the Wheat Industry

For thousands of years, all wheat, regardless of variety, was grown, harvested, and co-mingled in storage. As milling and the wheat food industry became increasingly sophisticated, companies became aware of the uniqueness and importance of wheat varieties. They now wanted to keep different classes and varieties of wheat separate at harvest and to identify which were best for what end use. For example, millers, bakers, and farmers all looked for different qualities in wheat. Thus, wheat manufacturers asked the question: Who should determine what qualities would be developed in new varieties?

**Milling.** Early millers were the first to begin to distinguish the unique qualities of different wheat species. They could tell in the milling process that all wheat was not the same. For example, some varieties of wheat were difficult to mill, produced less usable flour, and produced more "animal feed." Their customers also had increasingly sophisticated needs as baking became more mechanized. Cereal science isolated specific wheat and flour characteristics, and milling as a science and food technology had begun.

**Baking and wheat food industry.** Those who bake or prepare pasta, Asian noodles, crackers, tortillas, cakes, steam breads, and many other wheat foods long ago determined that all flour is not the same. Certain characteristics in various flours performed better when producing specific end products. Food companies need dependable flour for consistent products. After thousands of years, baking and wheat food industries have their specifications down to a science in regard to starch and protein content and a wide variety of other performance factors in various types of flour.

**Agriculture.** The farmer recognizes and needs wheat varieties that are resistant to plant, and soil, and airborne diseases and insects, that are suited to certain climates, and that are able to produce adequate bushels for the cost of production. There is very little monetary incentive provided by the food industry for specific wheat attributes. A farmer's source of profit is the production of the quantity of bushels that generate profitability for the farming operation.

**Gauging wheat quality.** Solutions to the various tensions surrounding wheat quality began in 1937. Under the bipartisan leadership of Mennel Milling in Michigan and Nabisco in New York, legislation was written that formed four wheat quality laboratories in the United States. These Agricultural Research Service laboratories

Goatgrass wheat is an ancient relative of cultivated wheat.

UNIVERSITY.

operate under the direction of the U.S. Department of Agriculture. Their goal is to guide the development of new wheat varieties to meet functional and nutritional needs of food processors while considering agricultural parameters for the growing regions they serve. In addition, representatives from milling, wheat food production and agriculture collaborate through the Wheat Quality Council.

### **Changes in World Wheat Production**

The world's yield per acre of wheat continually improves with the evolution of better wheat varieties and practices. World wheat production has nearly tripled since 1955 and has grown an average of 2.3 percent annually since 1951 (World Wheat Facts and Trends, 1998–1999).

Wheat needs continue to change. Great Britain traditionally grew soft wheat and once needed to import 2.75 million tons of higher protein wheat for bread flour from North America. Through wheat breeding, Great Britain now grows varieties suitable for bread flour and imports only 300,000 tons.

Many developing countries seek to be self-sufficient in their wheat needs. Over the past fifty years, India has achieved self-sufficiency and is now a wheat exporter. China, with nearly the same number of wheat-growing acres as India, has boosted its yields over a span of fifty years, becoming less dependent on imports. It is now the leading wheat producer in the world. Yields have increased from eight bushels per acre to thirty-five to sixty bushels per acre.

In past century in the United States there has been a dramatic decline in the number of farmers. In 1840, 70 percent of all Americans were engaged in farming. That number dropped to 12 percent by 1950 and to less than 2 percent by 2002. The cost of wheat production is simply not matched by returns in the marketplace. Despite having fewer farmers than it once did, the United States is second in world in production with Canada, Australia, the European Union, and Argentina being other major wheat contributors. Even though the faces involved in wheat production have changed, world wheat production continues to meet population growth and steady consumption demands.

### **The Wheat Trade**

The wheat trade reflects the unique ability of wheat to produce a wide variety of staple foods within diverse cultures. Wheat has come a long way from stone ground flat cakes baked on hot rocks, or gruel simmered over a fire. Asian noodles and steamed breads, chapattis, naan, baguettes, bagels, pasta, buns, crackers, biscuits, tortillas, and more all sustain the world's strong daily demand for wheat.

The wheat trade is not driven by market demand for wheat as an animal feed. Only an average of 16 percent of wheat is fed to animals worldwide. This number falls

to less than 4 percent in developing countries and may be as much as 35 percent in developed countries. Other commodities tend to fuel new industrial uses of wheat, such as ethanol and plastics production.

**Early wheat trade.** The early wheat trade followed trade routes in the Mediterranean, with Greece and Roman civilizations being some of the earliest importers of wheat from west Asian countries and Egypt. Wheat was undoubtedly carried on trade routes throughout those empires and into China via the Silk Road. Evidence of wheat in sunken cargo ships, religious writings, on pottery, and in the agriculture of northern Europe and Asia indicates the existence of an early wheat trade.

In the Middle Ages, the wheat trade became tied more closely with milling. For example, in Great Britain, the value of wheat was in its edible form, starting with flour. This tie was very pronounced from the ninth to eleventh centuries. Tenant farmers were compelled to mill their grain at their landlord's mill, and a "soke" of one-sixteenth of the production was kept by the landlord. Until the soke system died out in 1791, wheat was not sold much beyond the landlord's domain. Millers were tied to buying the varieties of wheat that were grown in their region. They welcomed the end of the soke system so they could import the wheat of their choice. In modern times some governments still restrict wheat imports by requiring their millers to buy domestic wheat, even if these varieties do not perform well in the end product.

The English Magna Carta (1215), borrowing from moral law, influenced the measures used in dealing in wheat over time. European countries had various systems of controlling the sale of wheat through warehousing, fixed prices, loans, and speculation (futures).

**Developing a world wheat trade.** After having wheat bread as a staple in Europe for thousands of years, settlers in the New World found no wheat upon their arrival. These settlers were dependent on imported flour from Europe, most often England, until they were able to produce wheat on their own. Though maize or Indian corn saved the early settlements, many English settlers viewed it with disdain. Out of necessity they would bake a bread called "thirds" to extend the precious imported wheat flour. This bread was prepared from one-third wheat flour, one-third rye, and one-third cornmeal.

Unlike silk or spices, shipping wheat throughout the world was not considered profitable. By the 1740s the United States was successfully exporting wheat to England from the northern fields of New York, New Jersey, and Pennsylvania. Shipments of wheat and flour were also sent, against British regulations, by defiant colonists to British, Dutch, and French colonies in the West Indies.

The role of the United States as a wheat exporter rose substantially after the American Revolution. Euro-

pean countries needed U.S. wheat due to crop failures in 1790 and 1807, and later in 1860–1862. Napoleonic wars and, later, World Wars I and II created record wheat demands.

**Government trade practices and agreements.** U.S. wheat exports experienced the largest decline in seventy years during the Great Depression and Dust Bowl era in the early twentieth century. Exports rebounded somewhat in the late 1930s until the rebuilding of Europe following World War II. As wheat production rose worldwide, wheat demand slackened.

The second half of the twentieth century saw enormous changes in world wheat production and the resulting wheat trade. Countries that were once centers in wheat production, self-sufficient for their wheat needs, became wheat importers. For example, west Asian countries, which were the cradle of wheat production (Afghanistan, Iran, Iraq, Saudi Arabia, Syria, Turkey, Yemen) and the earliest exporters of wheat to the Mediterranean and other early trade routes, imported 9.7 million tons of wheat in 1997. Countries such as India, not formerly known for wheat production, became notable wheat exporters. A new era began in the United States once wheat surpluses occurred. The U.S. government began to assume new importance in balancing the wheat trade.

All major wheat exporters employ a variety of trade-enhancement programs to maintain or increase their market share. Politics are an extremely important aspect of the functioning of these programs. Just one example is the grain embargo the United States placed on the Soviet Union in the 1970s. The United States watched its 49 percent market share of exports steadily fall to about 28 percent in 1998.

### EXAMPLES OF U.S. TRADE ENHANCEMENT PROGRAMS

- 1938: The U.S. government price-support program, the Commodity Credit Corporation, was formed.
- 1949: The International Wheat Agreement specifies quantities of wheat that could be sold abroad at a fixed range of prices.
- 1954: Agricultural Trade Development and Assistance Act or Public Law 480 allowed the U.S. government to make agreements for wheat sales or barter.
- 1959: Public Law 480 was amended to include long-term agreements and credit extensions for sales of surplus farm products.
- 1990: Export Enhancement Program (EEP) created.

### How Wheat Is Traded

Trade begins just after the wheat is loaded onto a grain truck or cart at harvest. Trade may even begin before the crop is grown if it is sold on futures or by contract. The following are the steps wheat takes in the market.

**Field to elevator or bin storage.** Wheat travels from the combine harvester in the field via truck or grain cart to storage bins on farm or a grain elevator (it may be a country cooperative elevator or a terminal elevator). Elevators are large storage facilities named for the moving belts used to move or “elevate” the grain. The elevator operator may purchase the grain or the farmer may store it for future sale. The wheat will be purchased according to its test weight, dockage, and grade.

**Grain inspection.** A seller would not want a buyer to refuse his or her grain due to a high level of moisture (14 percent maximum) or the presence of foreign material

TABLE 2

#### Top five wheat exporters

	Wheat production	2000 exports (in millions of tons)
United States	69.4	31.9
Canada	29	19.2
Australia	21.6	17.6
European Union	104.2	16.5
Argentina	12.3	12.5

(FM). If either of these things occurs, the price paid will be “docked” and it will have to be cleaned prior to storage or sale. These factors also promote insect infestation, decay, and other problems in shipment or storage.

Government or private inspectors examine samples from each load of wheat to record the wheat class, protein, moisture, and percentage of FM in the sample. Inspectors also grade the wheat for quality.

**Trade options: Cash for export or domestic use or futures contracts, government price supports.** A variety of wheat sales methods exists in the world. In the United States, wheat is traded on the floor of a grain exchange, which is where U.S. grain buyers and sellers meet. The grain exchange does not buy or sell wheat; rather, grain exchange members represent either the buyers or individuals or companies that sell grain. Buyers include millers, brewers, feed manufacturers, and exporters. The largest grain exchanges are in Chicago, Minneapolis, and Kansas City. Wheat is then purchased on either a cash or a “futures” basis. Futures markets originated with the Dutch tulip bulb trade in the 1600s. In the United States futures trading developed in Chicago prior to the U. S. Civil War. Selling wheat on a futures basis provides the producer a guaranteed price for a contracted future grain delivery date.

In many countries, if the price a farmer receives is too low to cover the cost of production it may be subsidized through a government agreement. Some governments subsidize grain transportation. In the United States, the subsidization is called a “deficiency payment.” An average cost of production is calculated and the difference between market price and the cost of production is the amount that the government will subsidize, within pre-set limits.

**Transporting grain to the customer.** After it is purchased, wheat will be moved out of or across the country to its destination via ship, train, or truck. Prior to delivery and upon arrival, the wheat is inspected for the specific tolerances of FM, moisture, and the class and grade listed in the contract. The wheat must be of a single class—no buyer will want wheat classes that have mingled.

**Fair trade practices.** International trade agreements are written by representatives from the trading nations involved. Representatives from trading countries negotiate trade practices through the General Agreement for Tariffs and Trade (GATT). The North American Free Trade Association (NAFTA) set guidelines for fair trade practices in that region. The European Union has laws and policies for fair trade. The agreements are meant to avoid the “dumping” of low-priced grain or price support practices that give one country an unfair advantage in the marketplace.

### The Future of Wheat

Ongoing wheat research and technological developments continue throughout the world. New wheat foods emerge weekly. Nutrition research continues to support wheat’s role as a food staple. Wheat components, such as fiber, starch, and gluten, are used in a wide variety of food products and pharmaceuticals. Wheat holds an important food-security role in a growing world population.

Ongoing wheat research includes many industrial applications in packaging, plastics, horticulture, and ethanol production, to name just a few. One of grain producers’ highest research priorities is finding a way out of the world’s reliance on petroleum.

## WHEAT AS A FOOD

The development of civilization may be directly connected to the cultivation of wheat. When humans no longer needed to roam the land to find animals, wild berries, and grains, villages arose. People could grow wheat in the warm months, store it throughout the winter for food, and set some aside for planting the next spring. It is not certain when civilization and the cultivation of wheat began, but anthropologists speculate it may have started in the Fertile Crescent of western Asia around 6000–8000 B.C.E. or earlier. This area between the Tigris and Euphrates Rivers is home to modern-day Iraq.

### History of Wheat as a Food

In about 17,000 B.C.E., human ancestors’ consumption of wheat consisted of chewing the hard kernels for sustenance. Eventually, they doubtless soaked whole or cracked wheat in water until it softened and swelled, making a porridge of sorts or providing the basis for a mixed dish much like tabbouleh salads. Pastes made from flour and water or milk were most likely one of the first staples of the early human diet. In about 10,000 B.C.E., the earliest recipe for a type of flat bread was invented: “pound wheat into flour, add water and bake.” Similar flat breads are still made in India (chapati), Mexico (tortillas), and in the Middle East (pita bread).

Einkorn, an ancient relative of wheat, was eventually domesticated and was popular until about 4000 B.C.E. There is evidence that more emmer (a wheat cousin) than wheat was grown at that time; emmer can still be raised in poor-quality soil in France, Italy, Turkey, and Yugoslavia. Einkorn and emmer were most likely eaten as a porridge before bread making was developed. After bread making became increasingly important, *Triticum vulgare*, another type of wheat, replaced einkorn and emmer. *Kamut*, which was found in King Tut’s tomb and is thus nicknamed “King Tut’s wheat,” was also cultivated in the Fertile Crescent area. It is still grown in limited quantities in the United States and is a registered trademark. *Kamut* is an ancient Egyptian word meaning “wheat.”

Egyptians are credited with having invented leavened bread. Archaeologists discovered what might be one of the oldest bakeries in the Giza Plateau of Egypt, dating back to around 4500 B.C.E. In his article “The Lost City of the Pyramids,” Mark Lehner speculates that such bakeries might have served workers building the pyramids. Honey was eventually added to bread for sweetening, and other flavorings such as salt, herbs, and seeds were also

Wheat becomes food when it is milled; thus, mills have been a center for wheat processing since ancient times. In colonial America, the miller acted as banker, since wheat was also used instead of cash for transacting business. This shows the old millstone in the restored nineteenth-century Murray Mill in Catawba County, North Carolina. COURTESY OF THE CATAWBA COUNTY HISTORICAL ASSOCIATION.

added. A form of this traditional bread recipe is often used to make sourdough breads either by airborne yeast or by adding yogurt with live active cultures.

The Romans discovered leavened bread long after the Egyptians. During the Second Punic War (218–201 B.C.E.) wheat was imported to Italy, and in the first century B.C.E. public bakeries were common. Wealthy Romans ate bread made from very finely ground flour, while the common people and soldiers survived on very coarse flour that was usually blended with other grains and broad bean flour.

### Religious Significance of Wheat

There are more than twenty references to bread in the Old Testament and over thirty in the New Testament. The first Biblical reference to wheat appears in Genesis 18: when three angels visit Abraham, he runs to his tent to ask his wife, Sarah, to make “cakes” of “fine meal.” (Fine meal probably referred to wheat flour that had been finely ground between stones.) Grinding stones have been found throughout the Middle East, as have sieves made from horsehair. References to wheat and bread also appear in sacred texts of Judaism, Hinduism, and Islam.

The Jewish people celebrate the eight days of Passover with unleavened bread, in the form of matzoh, to commemorate the Exodus from Egypt when they took only unleavened dough in their haste to flee. The Haggadah (a Jewish prayer manual) instructs its followers to declare: “This is poor man’s bread; the bread our forefathers ate when they were enslaved in Egypt.” During the rest of the year, every Jew is required to eat three meals on Shabbos, or the Sabbath: one on the night when Shabbos begins and two the following day, each of which must contain bread over which a specific blessing called the *motzi* is made. The traditional bread used at Shabbos is challah, an egg-enriched braided loaf (Fohrman, personal correspondence).

The Roman Catholic and Protestant churches usually use unleavened bread and wafers for the sacrament of Holy Communion; however, some churches (such as the Greek Orthodox Church) use leavened bread. In Islam, although they are not required by the Qur’an, the bulgur wheat-based soups *Jary* and *Shorobat Il-Jereesh* are traditionally used to break the fast during the observation of Ramadan (Solley).

### Worldwide Consumption of Wheat

Wheat is the most consumed grain in the world, with rice being a close second. China is the world’s largest producer of wheat. Almost every country in the world has some form of wheat-based bread, soup, or mixed dish in its culture. Numerous products overlap various countries and cultures because of migration. The following is by no means a complete list of all wheat-based foods that are available, rather it is a list of only some of the more well-known wheat products.

**Asia.** *Chapati*, a tortilla look-alike, is common in northern India and is usually made from whole-wheat flour and cooked on a *tava*, which resembles a grill. *Naan* is also an Indian bread that can be found in the Middle East and surrounding countries. It is a very soft round bread that is often coated with flour.

Asian noodles are often made from wheat, although they can also be made from buckwheat and rice as well. They do not contain egg and can be broadly divided into Japanese and Chinese types. Japanese noodles use regular salt whereas Chinese noodles use alkaline salt. Pot stickers are a popular Japanese dish whose base is wheat flour. They are small envelopes containing minced meats and vegetables and are fried or steamed.

**Europe.** Bagels originally came from Austria in 1683. Folklore says a baker was grateful to the King of Poland for saving Austria from invading Turks. He reshaped a local bread into the shape of the king’s stirrup and called it a *beugel*, derived from the German word for stirrup, *Bügel*. As bagels were brought to America, the word was changed to bagel.

Cookies came from the Dutch word *koekje*, meaning ‘little cake’. The British adopted them in the nineteenth

century and call them biscuits. Cookies eventually became a favorite in American diets.

English muffins are flat rounds of yeast-raised breads that are chewy with air pockets. One of its ancestors may have come from tenth-century Wales, called *bara maen*. English muffins are now popular throughout the Western world.

Gyro bread is a Greek pita bread that is wrapped around meats and vegetables to make the popular gyro sandwiches.

Pasta is an Italian word meaning paste, since it is made from durum wheat and water. The dough is then put through a variety of shaped sieves (there are over four hundred shapes worldwide) and cooked until dry. It can be served fairly plain with butter or olive oil or have any numbers of sauces piled on top. It can also be made into soups or casserole dishes such as lasagna. There is some controversy in regard to where pasta originated. Some have credited Marco Polo with bringing pasta back from China in 1255 C.E.; however, there is evidence that it was a staple in Italy before that time. Thomas Jefferson brought pasta to America, where it has also become a staple, in the late eighteenth century.

Pizza may have originally come from Italy, but it is no longer a strictly Italian product. Italian pizzas are much simpler than those found in the British Isles, Australia, New Zealand, and the United States. While traditional Italian pizza is not much more than a crust, tomato sauce, and sometimes cheese, the rest of the world heaps numerous meats, vegetables, and a variety of cheeses on their pizza crust.

Rye bread is a popular product in Northern and Eastern Europe. Rye crispbread is an essential part of Finnish army life and family diet even today. Soft, round, flat loaves with a hole in the middle, which in the old days were stored on horizontal poles under the ceiling in farmhouses, are made from rye through a fermentation process. The specialties of southwestern Finland and the archipelago are the soursweet loaf and malt bread. Island-baked bread is dark in color, and its northern counterpart may also have animal blood as an ingredient.

**The Middle East.** A variety of flat breads and bulgur soups are commonly eaten in the Middle Eastern countries. Bulgur (bulgar) is cracked, pre-cooked wheat that has about 5 percent of bran removed in processing. However, bulgur is still considered a whole grain product. It is the basis for tabbouleh salad and many stews and soups, and it can be eaten as a breakfast cereal. Bulgur can also be added to breads and muffins for extra texture and nutrition.

*Fatayer* are small bread-dough pies filled with meat, spinach, cheese, tomato, or onion. These are made especially for parties (Abourezk, p. 26). *Fettoush* was originally created to use up stale pita bread, but is now made from fresh, toasted pita bread. It is a salad of lettuce,

tomatoes, peppers, radishes, onions, squares of pita bread, olive oil, lemon juice, and several spices (Abourezk, p. 59).

*Lagymat* is a sweet mixture of flour, oil, leavening, yogurt, spices, and water. The batter is fermented and then spoonful portions are deep-fried. The golden brown products are cooled and dipped into syrup, which is usually flavored with cardamom and saffron.

Pita bread is a yeast-leavened flat bread that contains an internal pocket formed when steam puffs the bread up and then collapses before baking. Pita is often used as a “scoop” for dips or for stuffing with vegetables and/or meats as a sandwich.

Tabbouleh is a popular salad in the Middle East that has found a home in the Western world. It contains cooked bulgur, tomatoes, parsley, onions, and spices. Tabbouleh is often made as a social group activity as it requires a lot of chopping.

**Africa.** Couscous is very common in northern Africa but is not usually eaten in the rest of the continent. Couscous is a small, round product made from the same ingredients as pasta: semolina and water. It is precooked and needs only soaking in hot water to be ready to eat. Its bland flavor is often enhanced with spices and vegetables. It can be eaten as a breakfast cereal. Couscous is also becoming quite popular in North American restaurants.

*Kishk* (*kashk*) is often eaten in northern Africa and in the Middle East. It is a dried mixture of ground wheat and a heavily fermented dairy product. It is added to a variety of meals for taste and flavor. Moroccan whole-wheat bread is yeast leavened and actually is part white flour and is made into a round, flat bread.

**North America.** Biscuits were originally made in Europe and were twice-cooked, hard cakes that were the staple of sailors and soldiers for centuries. They are now a popular staple throughout southern United States and are light and flaky because of the fat content and the air beaten into the dough.

Cakes are popular sweet desserts and are used in traditional celebrations of birthdays and anniversaries. There are two basic types of cakes: those with fat (butter cakes) and those without (foam cakes). Angel food cake is the most common foam cake, whereas there are numerous popular butter cakes: chocolate, carrot, layered, and even some that contain frozen ice cream.

Corn bread is a favorite in the southern United States and Mexico. It usually contains some wheat flour as well as the cornmeal for volume and texture. It is often cooked in a hot iron skillet or corn bread mold for a darker, crisper crust.

Fry bread is a Native American bread that is still eaten in various parts of the country. The yeast-leavened bread dough is cut into squares and fried in hot oil and served with butter and sometimes honey.

The Roman goddess, Ceres, who was deemed protector of the grain, gave grains their common name today—cereal.

\*

The Chinese are more likely to steam or boil wheat foods rather than bake them. Steamed breads, pao, cakes, dumplings, and noodles are prepared in steamers or boilers rather than ovens.

\*

Even though airborne yeast was used as the leavening agent for thousands of years, it was not until the 1800s that yeast was actually identified as the organism that provided the leavening.

\*

A bushel of wheat weighs about 60 pounds (27 kg) and contains approximately one million individual kernels.

Pancakes are thin flat cakes made from a batter of water, flour, eggs, and leavening (usually baking powder or soda or a combination of the two). Pancakes are usually eaten for breakfast and sometimes called flapjacks, wheatcakes, or griddlecakes. Some form of pancakes can be found in most cultures.

Pies are a favorite dessert and come in all sizes and flavors. Fruit pies, such as apple, peach, and cherry are made in a pastry flour crust. They are usually eight inches in diameter and baked in a pie pan in the oven. Cream pies such as chocolate, coconut or banana are generally made in a flour crust or graham cracker crust.

Quick breads, such as zucchini, carrot, and banana breads, are sweet loaves that are leavened with baking powder and/or soda and appear to be native to the United States. Muffins are also considered a quick bread although they are made in individual muffin pans or paper cups for single servings.

Sourdough became a staple for the gold miners and other pioneers in the west and northern parts of North America. These individuals could carry a “starter” of yeast, flour, and water from camp to camp and then add water and warmth at the next campsite to make bread. From each batch they would save a starter for the next batch. This practice earned miners, shepherders, and mountain dwellers the nickname “Sourdoughs.”

Tortillas are probably the fastest growing wheat product in North America. The original unleavened flat bread was made from corn in Mexico and Central and South America. Wheat tortillas are now the largest category sold in the United States. The word tortilla comes from the Spanish word *torta*, which means ‘round cake’.

White pan bread, hamburger, and hot dog buns are the major wheat products sold in North America. One hundred percent whole-wheat products consist of less than five percent of sales, but sales of whole wheat and partial whole grain products are growing faster than white breads.

**Australia and New Zealand.** In this part of the world, wheat flour is used in the production of many Western products in addition to their unique meat pies and sausage rolls. Meat pies are usually about three to four inches in diameter, may be square or round, and consist of a pastry base and cover that encloses a filling of cooked minced meat (often beef) and gravy. Sausage rolls are usually about four inches long and about one-and-a-half inches wide and consist of seasoned sausage filling that is rolled in flaky pastry and then baked.

**South America.** *Alfajores* are desserts popular in Peru and Chili. They are made from wheat flour and vegetable shortening and baked. When served, they are layered with *manjar blanco* and topped with confectioner’s sugar. *Manjar blanco* is condensed milk that is slowly cooked until it thickens and becomes brown.

Empanadas are baked or fried and filled with a variety of meats, cheeses and vegetables. Empanada literally means ‘wrapped in bread’, although it is often a pastry dough rather than a bread dough.

The South American *paneton* is similar to the Italian Christmas cake. It is a wheat bread containing pieces of citron and sugar-glazed on top. In Peru, it is eaten on Christmas Eve with hot chocolate beverages.

### Classes of Wheat

A variety of wheat classes are grown throughout the world, but six major varieties are grown in the United States. They are:

**Hard red winter wheat**—This is primarily grown in the “bread basket,” the Midwestern states of Kansas, Nebraska, Oklahoma, Texas, Colorado, and Wyoming. South Dakota and Minnesota also raise some hard red winter wheat. It is primarily used for breads and all-purpose flour.

**Hard red spring wheat**—This type of wheat is grown mostly in the upper, colder states such as North Dakota, Minnesota, and Montana. It is primarily used for breads and croissants.

**Durum wheat**—Durum wheat is grown primarily in North Dakota, with additional supplies coming from Montana, South Dakota, and Minnesota. Arizona and California grow a desert durum variety. Durum is used primarily for pasta.

**Hard white wheat**—This is the newest class of wheat grown in the United States. It is raised to some extent in all of the major wheat states and is used for breads and Oriental noodles.

**Soft white wheat**—This wheat is grown primarily in the northwest states of Washington, Idaho, and Oregon. This wheat is used for pastries, crackers, cereal, cakes, cookies, and Oriental noodles.

**Soft red wheat**—Soft red wheat is grown in eastern parts of the United States, it is used in cakes, cookies, and crackers.

### Kinds of Wheat Flours

Commercial bakers require several types of flours to be milled to specification for use in the end products they will produce. Home bakers are most likely to use all-purpose, cake, bread, and whole-wheat flour. Serious bakers will even use pastry and semolina in their baking.

**All-purpose flour**—This is the finely ground endosperm of the wheat kernel and is often a blend of hard and soft wheat that produces a flour suitable for many types of products. All-purpose flour is usually bleached, which does not affect the nutritional value, but it does improve the baking qualities for cakes and cookies.

**Bread flour**—This flour comes from hard wheat, because of its strong gluten strength that will hold the framework of a loaf of bread. Bread flour is usually unbleached.

**Cake flour**—Cake flour is the finely ground endosperm of soft white and soft red wheat. It is usually bleached and is used for cakes, cookies, crackers, quick breads, and some pastries. It has a lower gluten content, which makes the products more tender.

**Durum flour**—The finely ground endosperm of durum wheat, durum flour is usually found in specialty sections of supermarkets or health food stores. It is used primarily for making noodles.

**Gluten flour**—Gluten flour is milled from hard wheat and is a high-protein (gluten) flour. It contains about 45 percent protein, whereas bread flour is usually about 12–14 percent protein. Gluten flour is added in small amounts, one tablespoon per one pound loaf, when making bread at home. Commercial bakeries use it to strengthen their bread flour if necessary.

**Pastry flour**—This type of flour is not as common for the home baker as it is for the wholesale baker. It also is made from soft wheat to make a tender, fluffy pastry crust.

**Self-rising flour**—Self-rising flour originated in the southern part of the United States and is the oldest “mix” found in America. It is an all-purpose flour with appropriate amounts of leavening and salt added to make quick breads. A cup contains one-and-a-half teaspoons of baking powder and a half-teaspoon of salt.

**Semolina**—Semolina is a coarsely ground endosperm of the highest quality durum wheat and is used

for making pasta, although it can be used for making bread because of its high gluten quality.

**Whole-wheat flour**—Whole-wheat flour is also called graham flour and stone-ground flour. Whole-wheat flour is ground from the entire kernel containing the bran, germ, and endosperm.

### Nutritional Value of Wheat

Wheat is the most consumed grain in the world, providing both calories and nutrients for the growing population. Wheat is a significant source of complex carbohydrates, dietary fiber, plant protein, phytochemicals, antioxidants, vitamins, and minerals. On a per-capita basis in 1995, Germans consumed 187 pounds of bread, while U.S. citizens ate only 53 pounds each. Many countries consume a considerable amount of wheat each year. The United States eats about 150 pounds of wheat flour per person annually, whereas Chile consumes 214 pounds; Pakistan consumes 334 pounds; the European Union averages 160 pounds; the East Africa region eats about 250 pounds; and China consumes an average of 221 pounds per person annually.

Whole-wheat products such as cereals, breads, pastas, tortillas, English muffins, and other products are extremely healthy. The American Dietetic Association recommends consuming three servings a day of whole-grain product foods (wheat, barley, oats, corn, rye, etc.).

In July 2000, the following whole-grain health claim was approved by the U.S. Food and Drug Administration (FDA) Center for Food Safety and Applied Nutrition: “Diets rich in whole grain foods and other plant foods low in fat, saturated fat and cholesterol may reduce the risk of heart disease and certain cancers.” In addition to helping to prevent heart disease and some cancers, preliminary research shows that whole grains might also help prevent the onset of type II diabetes.

In some countries throughout the world, refined grains are offered to the consumer without any nutrient enrichment. This is a disservice to the public since the product, in that state, has fewer nutrients to offer. In some countries, however, vitamin A is added to help prevent blindness in children. In several Western countries, three B vitamins—thiamine, riboflavin, and niacin—and iron are added in the same amounts found in whole-wheat flour. In 1998, the United States required that enriched grains also be fortified with folic acid, a B vitamin that (among other benefits) may reduce the chances of certain birth defects. Between 1998 and 2001, after the mandatory fortification of wheat was put into effect, neural tube birth defects dropped 19 percent in the United States (Honein et al.). Preliminary studies have also shown that folic acid is effective in reducing homocysteine levels in the blood. High levels of homocysteine are believed to contribute to heart disease, strokes, and Alzheimer’s disease. Although more research must be done, there is positive indication that folic acid may also be effective in helping to prevent cleft lip and palate, Down’s syndrome, and several cancers.

Enriched flours are often bleached for two reasons: to lighten the flour and to improve baking qualities. Bleaching oxidizes the gluten slightly and therefore makes cakes and pastries more tender. Breads, on the other hand, need strong gluten, so bread flour and gluten flour are rarely, if ever, bleached. When flour is bleached, it is exposed to chlorine gas and benzoyl peroxide. No residues of these substances are left in the flour, however, so there is no nutritional difference between unbleached and bleached flour.

A small percentage of people cannot tolerate the gluten (protein) in wheat because they lack the enzymes to digest it. This disease is known as non-tropical celiac sprue, and those who have it cannot eat wheat, rye, or barley. Some experts recommend they eliminate oats also; however, the latest thinking is that oats may be safe.

### Biotechnology and Wheat

As of the start of the twenty-first century, no genetically engineered wheat was available on the market, but such products were in development. The first genetically engineered wheat would primarily benefit the farmer and the consumer by using fewer pesticides during the growing period.

**WHISKEY (WHISKY).** The spelling "whiskey" is common for Irish whiskeys and the vast majority of U.S. whiskeys. The spelling "whisky" is sometimes used for Scotch, Canadian, and other whiskeys and occasionally for some U.S. whiskeys. The word "whisky"/"whiskey" is derived from the Irish and Scottish Gaelic *uisquebaugh* or *uisge beatha*, meaning 'water of life' (compare the French *eau-de-vie*). Whiskey is of course a high-alcohol beverage ("spirit") produced by the distillation of grain-based lower-alcohol fermentations.

### Origins and Social History

The art of distillation of various fermented brews, most often wine-based, dates back to ancient civilizations, including Chinese, Indian, and Egyptian. Much of the European Middle Ages saw distilled alcohol used medicinally, but undoubtedly a proportion of early distillations was consumed as a warming, mood-uplifting drink. It is likely that whiskey-type distillation originated in Ireland, possibly as early as 500 to 800 B.C.E. and mainly within monastic communities. Irish Gaels emigrated to western Scotland and beyond, and it is likely they took their craft with them. Distilling the brews of grains, usually from their own land, was largely a home-based craft among Highland clans for personal consumption. What is referred to as Scotch whisky was first specifically listed in print around 1500.

Home distilling for personal consumption remained legal until 1784, but long before then whisky was sold or traded illicitly. However, greater problems developed with the introduction of taxes on spirits. Following the "union of the Crowns" in 1603 (King James VI of Scotland inherited the English throne as King James I of England and Scotland), whisky distilled in Scotland became more popular in England. However, England and Scotland maintained separate Parliaments with individual legal systems and laws. The "republican" English government (the Commonwealth years of Oliver Cromwell) imposed the first tax on spirits in 1643. Under duress, the Scottish Parliament followed suit the following year and levied an additional high duty in 1693. The British monarch Charles II also attempted to tax Irish whiskey in 1661 but with little success.

The Act of Union (the union of the Scottish and English Parliaments to become the British government in London) in 1707 brought more serious problems for Scottish (and, to a lesser extent Irish) whisky in the eighteenth century. More duties were levied, but the vast majority of distillers avoided paying taxes. The numerous excisemen found collection difficult as most distilling was still small scale, often in remote Highland glens, and illegal stills were easy to dismantle and relocate. Smuggling, often undertaken during darkness, was widespread. Even when illicit distillers were brought to court, magistrates were often sympathetic and lenient, imposing low fines.

A selection of American whiskeys distilled in or near Bardstown, Kentucky. PHOTO BY PHILIP GOULD, 1991. © PHILIP GOULD/CORBIS.

Robert Burns, Scotland's national bard worked as an exciseman for some eight years before his death in 1796. He was a devotee of whisky and its warm, merry, and creative effects. He wrote several poems and songs in praise of whisky, such as "The Deil's Awa' Wi' th' Exciseman" (The devil's away with the exciseman). A few choice lines give the flavor (English equivalents of Scots words are in parentheses).

We'll mak [make] our maut [malt], and we'll brew our drink,

We'll laugh, sing, and rejoice, man, . . .

. . . There's threesome reels, there's foursome reels,

There's hornpipes and strathspeys [dances] man,

But the ae [one] best dance e'er [ever] cam [came]

to the land

Was the deil's awa' wi' th' Exciseman.

By 1823 new legislation completely altered the development of Scotch whisky distilling. The change from heavy taxation, calculated by volume, to a reasonable license fee encouraged larger distilleries in more permanent locations.

A somewhat similar history applies to American whiskey. Following the English Pilgrims, further immigrants included Scots and Irish, who spread westward to farm. As their yields of grains increased, many settlers made their own whiskey from barley, rye, and upon further expansion west, corn. British taxes were introduced as early as 1684, with little success in collection. In 1791 Pennsylvania passed a law requiring registra-

tion of all distilling equipment. A few years later an outright rebellion erupted in Pennsylvania, including destruction of property and capture of excisemen, that was only quelled by the militia. As in Scotland, larger commercial distilleries, including those in Pennsylvania, Tennessee, and Kentucky, began to take over during the nineteenth century.

### Raw Materials and Basic Processes

Scotch whisky can be divided into two basic types, malt whisky and blended whisky. The former, original type uses barley exclusively, whereas blended whisky combines malt whisky with spirits from other cereals.

**Malt whisky.** The harvested and dried barley is first "malted," that is, the grain is allowed to germinate to a certain point. This is achieved by soaking in water for a controlled period (two to three days), draining the water, and airing and turning the germinating grains at a controlled temperature (around 60°F). The last process usually involves large revolving drums. The grains are soft, and germination is stopped. During germination, enzymes convert insoluble starch to soluble. This "green malt" is dried, which in most cases includes various periods of peat-fire smoke (peat originates from the decomposition of vegetable matter). The dried malt is coarsely ground, and hot water is added. This process of "mashing" converts soluble starch to the sugar maltose. The liquid is drawn off, cooled to around 70°F, and run into fermentation vessels along with yeast, mainly from brewers but often including cultures of selected strains.

Distilling *poteen* (illegal whiskey). The home distiller is shown here straining the mash. Photo by Michael St. Maur Sheil, taken at an undisclosed location in the Republic of Ireland, 1996.  
© MICHAEL ST. MAUR SHEIL/CORBIS

Fermentation is vigorous and rapid, usually thirty-six to forty-eight hours, with the yeast converting sugars to alcohol (7 to 8 percent).

This liquid is then distilled in pear-shaped copper ("pot") stills, first in large stills to produce crude "low wines" with around 30 percent alcohol. This is redistilled in smaller stills with precise care to minimize impurities (such as alcohols higher than ethanol), producing pure but immature spirits of around 70 percent alcohol. A few Scotch and most Irish spirits are distilled a third time, finishing as lighter whiskeys.

These "rough" spirits require maturation and are transferred to oak barrels, often with water added to reduce the alcohol content to around 63 percent. Various types of oak barrels, such as bourbon, sherry, and Madiera casks, contribute color and flavor from the wood. Although by law the minimum storage is three years, five years is more common (mainly for blending), and most superior malts are matured ten to fifteen years or longer.

**Blended whisky.** This type added enormously to the amount of Scotch produced in the nineteenth century

with the design of a much larger still. The blends are a mixture of a wide variety of malt whiskies with "grain whisky," which is distilled from a range of grains, including corn, rye, wheat, and barley, mainly unmalted. The large stills used are modified versions of the Coffey stills (patented in 1830), which distill continuously and produce a purer 90 percent alcohol. Blending the many types of malt whiskies is a skilled occupation, accomplished by an experienced nose. Generally lighter- to fuller-flavored blends are related to the increasing proportion of malt whiskies used.

### Twentieth-Century Developments

Apart from new varieties of barley and other cereals, centralized and mechanical maltings, and novel designs of Coffey stills, whiskey production is essentially traditional. In the twentieth century prohibition in the United States provided opportunities for increased production of Scotch, Irish, and Canadian whiskeys. Whiskey production has spread to many countries, especially Japan, which already had a traditional base and which offers brands that are prized among the world's elite. Larger companies and mergers have also resulted in conglomerates. Surprisingly, given the long tradition, production and marketing of single malt Scotch whiskies increased strongly only since the 1960s. Quite a number of malt whisky distilleries in Scotland are owned by U.S., Canadian, and Japanese companies, for example, Jim Beam, Seagrams, and Suntory respectively.

**WIC (WOMEN, INFANTS, AND CHILDREN'S) PROGRAM.** The Special Supplemental Nutrition Program for Women, Infants, and Children, commonly referred to as WIC, is a Federally funded nutrition-intervention program administered by the Food and Nutrition Service of the U.S. Department of Agriculture. WIC began as a two-year pilot program in 1972 under an amendment to the Child Nutrition Act of 1966, and

was made permanent in 1974. Its mission is to provide supplemental food, nutrition education, and health-care referrals to low-income pregnant or postpartum women, their infants, and children up to the age of five, to improve their health outcomes.

WIC is available in all fifty states, the District of Columbia, thirty-two Indian Tribal Organizations, Puerto Rico, the Virgin Islands, American Samoa, and Guam. WIC is the third-largest national food assistance program, following the Food Stamp and National School Lunch programs, and accounts for 12 percent of total Federal expenditures in this area. In fiscal year 2001, WIC served an average of 7.3 million participants per month, 75 percent of whom were infants and children; annual expenditures exceeded \$4 billion (see Table 1). WIC does not guarantee participation for all eligible women, infants, and children who apply, and the number of people the program serves is determined by annual levels of Federal funding. In recent years, WIC has been fully funded, and all eligible persons have been able to participate.

To qualify for WIC, applicants must first meet income guidelines and a state residency requirement, and they must be at nutritional risk as determined by a doctor, nurse, or nutritionist. Guidelines state that the gross income of the applicant must fall at or below 185 percent of the Federal poverty-guideline figure, although each state can reduce income-limit standards. Participants in other benefit programs such as the Food Stamp Program, Medicaid, or Temporary Assistance for Needy Families automatically meet income requirements. To be at nutritional risk for WIC, one must have either a medically based risk such as underweight, anemia, or previ-

ous poor pregnancy outcomes, or a diet-based risk such as a dietary pattern deemed inadequate compared with U.S. Dietary Guidelines.

Participants in WIC receive benefits in the form of checks, vouchers, or electronic benefits transfer (EBT) cards that are redeemable monthly at certain retail food stores. In 2001, average monthly benefits per person were about \$34. Participants may use these benefits to purchase specific foods designated as important to supplementing the diet of this population. Only nutrient-dense foods that are high in one or more of particular nutrients—protein, calcium, iron, and vitamins A and C—are included, although the food package is not intended to fulfill all of the nutrient needs of the participants. Examples of foods available using WIC include iron-fortified infant formula, iron-fortified infant and adult cereals, fruit or vegetable juice rich in vitamin C, eggs, milk, cheese, peanut butter, dried beans or peas, tuna fish, and carrots. Foods are substituted where there are medically necessary dietary modifications. Participants also receive nutrition education and necessary referrals to health-care services.

WIC is one of the most cost-effective and successful nutrition-assistance programs in U.S. history. Several studies have concluded that, for every \$1 spent on pregnant women under WIC, between \$1.77 and \$3.13 in Medicaid costs were saved over the first sixty days after childbirth. Research consistently shows that WIC participation results in improved birth outcomes and savings in health-care costs, improved diet and diet-related outcomes, improved infant-feeding practices, increased immunization rates, and improved cognitive development for children.

### WIC Program Participation and Costs

Fiscal Year	Total Participation (Thousands)	PROGRAM COSTS (Millions of Dollars)			Average Monthly Benefit Per Person (Dollars)
		Food	NSA	Total	
1974	88	8.2	2.2	10.4	15.68
1975	344	76.7	12.6	89.3	18.58
1980	1,914	584.1	140.5	727.7	25.43
1985	3,138	1,193.2	294.4	1,489.3	31.69
1990	4,517	1,636.9	478.7	2,122.2	30.20
1995	6,894	2,516.6	904.9	3,441.4	30.41
2000	7,192	2,852.2	1,102.6	3,971.1	33.05
2001 (P)	7,306	3,007.8	1,114.3	4,153.0	34.31

NSA = Nutrition Services and Administrative costs. Nutrition Services includes nutrition education, preventative and coordination services (such as health care), and promotion of breastfeeding and immunization. In addition to food and NSA costs, Total (under Program Costs) includes funds for program evaluation, Farmers' Market Nutrition Program (FY 1989 onward), special projects, and infrastructure.

## WINE.

*This entry includes five subentries:*

Overview

Wine in the Ancient World

Wine from Classical Times to the  
Nineteenth Century

Wine in the Modern World

Wine, Nongrape

### OVERVIEW

Wine is an alcoholic beverage made by fermenting grape juice. Although the juice of other fruit, berries, and vegetables can be fermented to create alcohol, fruit wines are generally qualified by the name of the produce used, such as gooseberry wine and blueberry wine. The word “wine” when used alone refers to an alcoholic beverage made from grapes. Wines come in various colors (red, white, rosé) and many types, which include dry and sweet, still and sparkling, and wines fortified with grape spirit (brandy). There are also many wine-based drinks, such as wine coolers and sangria.

### Grape Varieties

Although wine can be made from any kind of grape, not all grape varieties are suitable for making good quality wine—wine with acceptable taste and capable of lasting in good condition for several years. Most of the world’s wine is made from one species, *Vitis vinifera* (meaning “a wine-bearing vine”), which is native to Europe and the Middle East. Most of the grapes used for making commercial wine are members of this species, and they include such common varieties as Chardonnay, Riesling, Sauvignon Blanc, Merlot, Pinot Noir and Cabernet Sauvignon, and Syrah/Shiraz.

Other grapes also used for making wine include varieties such as Concord, Alexander, and Catawba, which are members of the *Vitis labrusca* species that is indigenous to North America. Additional varieties have been created by breeding two varieties of the same species (called crosses) and by breeding two varieties of different species (called hybrids). Thus the Dornfelder variety was bred from two *Vitis vinifera* varieties and is a cross, while Baco Noir, bred from a variety of *Vitis vinifera* and a *Vitis riparia*, is a hybrid.

The many reasons for breeding new varieties include creating grapes with particular flavor profiles, grapes that ripen early (important in regions with short growing seasons), or vines that are tolerant of colder climates. In addition to crosses and hybrids, vines generate clonal variations spontaneously, with each clone having slightly different growing, taste, or other characteristics.

Many hundreds of grape varieties can successfully be used for making wine, and the list seems even longer because some varieties can have different names in different places. For example, the grape known as Syrah in France is called Shiraz in Australia, while the Malbec variety has many alternative names, including Cot, Pressac, and Auxerrois. Some variations in name simply reflect language (Pinot Gris is known in Italy as Pinot Grigio) while others reflect the origins of the grape (Burgundy’s Pinot Noir is known in Germany as Spätburgunder).

It is likely that wine was originally made (in the Neolithic period, 7,000 years ago) from wild grapes, and that when farmers began to cultivate vines for wine, they selected grapes that seemed particularly suitable. The selected grapes would have had a high ratio of pulp to seeds and might have given better flavors than other grapes.

### Characteristics of the Grape

Grapes contain or bear everything that is needed to produce wine; each grape is effectively a microwinery. The most important parts of the grape are the pulp, which contains water, sugar, fruit acids, and pectin, and the skin, which contains color pigments, flavors, and tannins. The skin also carries wild yeasts that occur naturally in the vineyard. The other parts of the grape, which are less often important for winemaking, are the stem (which contains tannins) and the seeds or pips (which contain tannins and bitter oils).

Tannins are compounds that occur naturally in grapes and other products and that give a drying feel when they come into contact with the mouth. Swishing cold, strong black tea, which is high in tannins, will make the mouth and gums feel as if they are contracting with dryness. Tannins are preserving agents (used to tan skin and turn it into leather), and in wine they are a natural preservative that allows a wine to age without degrading. Young wines meant for long-term cellaring can be high in tannins and, over time, the feel of tannins softens.

Although the winemaking process is very important, such that the same grapes made into wine by two differ-

ent winemakers can taste significantly different, the grape variety is the single most important factor. Like other fruit, varieties of grapes differ from one another in many ways. Some have thick skins and some have thin, which can be important for their relative ability to withstand disease and for the degree of flavor and tannins they have. Some varieties develop a higher ratio of acid to sugar (just as more acidic Granny Smith apples differ from the sweeter Red Delicious variety). Some grapes (such as Cabernet Sauvignon) naturally have more tannins than others (such as Gamay). The sum of each grape variety's characteristics is the primary influence on the character and flavor of the finished wine it makes.

### Environment

A second set of influences on wine is the environment in which the grapes grow: especially the soil and climate. The total environment is sometimes referred to as the *terroir*, a term that includes the composition of the soil (topsoil, bedrock) and its nutrient, drainage and heat-retention properties; climate (annual temperature, hours of sunshine, precipitation, frosts, winds); geographical features (such as forests, mountains, rivers, bodies of water) that influence climatic patterns; the slope of the vineyards (on steep or gentle slopes or on plains); and aspect (angle to the sun, direction of slope).

Slope can be important because the most interesting and complex grapes seem to grow on vines that are stressed, which is to say that they must struggle for water and nutrients. The best soils for vineyards are not the rich, fertile humus suitable for other produce, but often hard, stony or sandy soils that are well drained (which is why slopes are often ideal). Vines can also be stressed by planting them closer together so that each has to compete with others.

*Terroir* has become an article of faith for many producers, who argue that the flavors and other qualities of a wine express the *terroir* in which the grapes were grown. Some producers (particularly in regions like Burgundy) insist that wines made from vines grown a few feet apart taste distinctly different. Some ardent advocates of *terroir* include in it not only the physical and environmental character of a specific site, but also the tradition of vine growing and the soul of centuries of winemakers.

### Viticulture

Cultivation practices (viticulture) are also very important in that they can modify the environment. Density of plantings and types of trellising can have an impact on the exposure of vines to nutrients and sunshine. Canopy management, the removal of some foliage, can increase the ripening potential of grapes. Irrigation (which is not universally permitted) can make up for shortages in natural water supply, while excess water can be dealt with by burying drainage tiles to increase the flow of water away from vine roots. Some viticulturalists even modify the soil by digging in rocks (which absorb heat during

Wine is not only a beverage but is also used as an ingredient in cookery. This nineteenth-century American cake tin was used for making Madeira cake, a popular food for teas and fancy suppers. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

the day and radiate it at night) and spreading dark soil, which attracts more heat than lighter-colored soils.

### Yield

An important influence on grape character is yield, which is often expressed as the number of tons of grapes harvested per acre of vines or the number of hectoliters (one hectoliter is 100 liters) of wine per hectare (about 2.4 acres) of vines. In general terms, the lower the yield, the more flavorful and complex the wines. Yields are often reduced by "green harvesting," which involves picking (and throwing away) a proportion of the bunches of grapes on each vine before they begin to ripen. This allows the smaller number of bunches remaining to benefit from all the nutrients the vine absorbs. Some national and regional wine laws (see below) set maximum yields on vines.

The same principle underlies the value attributed to "old vines," a quality that is sometimes shown on labels. As vines age, they begin to bear fewer bunches so that, without human intervention (like green harvesting), their fruit tends to be of higher quality. There is, however, no regulated definition of what constitutes an old vine, and, depending on varietal and producer, it can mean a vine from fifteen to eighty and more years old.

### Pests and Diseases

Finally, viticulturalists have to decide on what methods to use to deal with vineyard pests and diseases. Pesticides and other chemicals (notably sulfur) are widely used to control insect infestation and vine diseases but, for

environmental and financial reasons, their use is declining in many regions. Some producers have adopted organic practices and, depending on wine or agricultural law, can label their wines organic.

### Climate

Clearly *terroir* and cultivation practices interact with grape variety in that some varieties do best in specific climatic and other growing conditions. Riesling, for example, does best in cool climates that preserve the acidity so highly valued in Riesling wines, even if the alcohol level is often below 12 percent. Zinfandel, on the other hand, thrives in warm regions where it produces wines high in alcohol (often 14 percent and higher) with rich, ripe fruit flavors and relatively low acidity.

All these characteristics have an important bearing on the quality of the grapes grown in any specific region. In general terms, warmer regions (like South Africa and many regions in California) produce riper grapes with higher sugar content that have the potential of producing deep-colored, high-alcohol wines (13% and higher). Cool climate regions with shorter growing seasons (like Germany and northern France) tend to produce paler, more acidic wines that are lower in alcohol (12.5% and less). Vines on south-facing slopes in the Northern Hemisphere benefit from more sun, but there are some places (in Greece, for example) where vines are grown on north-facing slopes so as to moderate the effect of the sun's heat.

*Terroir* is not constant. Although soil characteristics change very slowly over time (unless there is human intervention), climate experiences annual variations that range from modest to dramatic. One summer in a given region might be dry and hot, the next cool and wet. There might be a late frost, a summer hailstorm, and an early winter or Indian summer. These variations can affect and make diseases of the vines more or less likely. Hot, humid conditions can lead to molds and mildews. Weather conditions can lead to lower or higher yields and can affect the ability of grapes to ripen and develop the desired levels and balance of sugars, acids, tannins, and other properties.

Annual weather variation is the reason that so much attention is paid to vintage. The vintage of a wine is the year the grapes were harvested, and knowledge of the weather conditions in a region in a given year will reveal much about the potential quality of the wine made in that region that year. Some years stand out for the quality of the wine produced, whether it is good or bad. For example, 1997 is considered to be an excellent year for Tuscan wines (including Chianti) but a poor year for most of the districts in Bordeaux. But weather conditions that might be negative for one grape variety can be less so for another. So in a region like Bordeaux, where three principal red grape varieties are grown, and where the red wine is a blend of up to five different varieties, producers can consider the quality of each variety when deciding on the blend.

### Harvesting

Decisions about vine variety, vineyard location, and cultivation practices are made so as to maximize the quality of the fruit at the point that it is judged optimal for harvesting. Harvesting itself involves myriad decisions. Grapes can be harvested by hand or by machine, by bunch or by individual berry. Some vineyards are entirely harvested in one go, while others are harvested in several runs (*trís*) over a period of days, with only the ripest bunches or grapes being picked each time. Most harvesting is done during the day, but some producers practice night harvesting, when the cooler temperatures allow grapes to be picked and transported to the winery in temperatures that help preserve their freshness.

It is a cliché among winemakers that “wine is made in the vineyard.” This means that good quality wine can be made from only good quality fruit, and that what goes on in the vineyard is more important to wine quality than what happens in the winery. Yet just as the quality of the grapes results from scores of decisions related to grape variety, vineyard site, and cultivation practices, so the winemaker makes scores of decisions that affect the quality and character of the finished wine. It takes an able winemaker to make high-quality wine from even the best quality grapes.

### Fermentation

Wine is made by crushing the grapes so that the yeasts on the skin (or cultured yeasts introduced by the winemaker) come into contact with the sugars in the pulp. This initiates fermentation, the process by which the yeasts consume the sugar and produce alcohol and carbon dioxide. Fermentation is the central part of winemaking but it is preceded and followed by several other stages, and the methods of carrying them out influence the taste and character of the finished wine.

The grapes are first crushed or pressed so as to extract the juice. Old methods of treading grapes by foot or pressing them in manually operated screw presses have virtually disappeared, and most commercial wines are made from grapes crushed in mechanical presses. Many producers prefer pneumatic bladder presses, which crush the grapes gently and do not release the bitter oils in the pips.

If white wine is being made from black or other dark-skinned grapes (nearly all of which have pale-colored pulp), the must (unfermented grape juice) is quickly drawn off the skins and other solids so that the color pigments they contain do not dye it. For red wine (which can be made only from dark-colored grapes), the must is left in contact with the skins so as to draw color from them. Winemakers who want to make very dark wines (which are increasingly popular) sometimes use enzymes to extract all possible color from the skins so as to dye the juice deep red.

Naturally occurring yeasts can be used for fermentation, but because they tend to be unpredictable (in

terms of when they start fermentation and the speed of fermentation), many producers use more reliable and predictable cultured yeasts. Length of fermentation can affect the flavor of wine, as can the temperature. Fermentation is a naturally hot process, and some wines are “cool fermented,” meaning that the fermentation tanks or barrels are artificially cooled during fermentation. Cool fermentation tends to preserve the fresh, fruity flavors in wine.

Most fermentation takes place in stainless steel vats, but some wines are fermented in oak barrels. This adds additional flavor to the wine although it does not, as many people expect, make the finished wine taste “oakier” than wines that are simply aged in oak barrels. Whether in vat or barrel, the carbon dioxide produced during fermentation is allowed to dissipate into the air.

Fermentation is generally complete when the yeasts have consumed all the sugar, resulting in a wine that is “dry” because it contains no residual sugar. But fermentation can also terminate when the alcohol level in the wine reaches a level that kills the yeasts, generally at an alcohol level of about 16 percent. Any sugar not fermented by that stage remains in the wine, giving it a degree of sweetness depending on the percentage of residual sugar. In some specific wines, fermentation is deliberately terminated before all the sugar is fermented. For example, Port and some other sweet, fortified wines are made by adding grape spirits (brandy) during fermentation. This raises the alcohol level and kills the yeasts before they ferment all the sugar in the must, resulting in a wine that is sweet and has a higher alcohol level than it would have achieved without the added spirits.

Wines can also undergo secondary fermentation. The most common is malolactic fermentation (MLF) in which the harsher malic acid in the wine is turned into softer lactic acid. This is commonly used for white wines and produces the softer feel of the wine in the mouth that is sometimes described as “buttery.” Some red wines also undergo malolactic fermentation.

Champagne and sparkling wines made in the “Champagne method” or traditional method undergo secondary fermentation in the bottle. Sugar and yeast are added to a base wine in the bottle so that fermentation re-starts, but the bottle is capped so that the carbon dioxide produced during the process is trapped inside rather than dissipating. Unable to escape, the gas is dissolved into the liquid. Later, the dead yeast cells are removed and the bottle is topped up and corked, all without releasing the gas. It finally escapes, in the form of bubbles, when the cork is removed.

The sugar level of the grapes at the time of harvest determines the potential alcohol level of the finished wine. Several different scales are used to measure the concentration of grape sugars (the must weighty). A widely used (American) scale is Brix, and in approximate terms, grapes make wine with a percentage of alcohol roughly

half the Brix level. More precisely, grapes with 23.7 Brix will make wine with a potential alcohol of 12.5 percent. Other scales for measuring must weight are degrees Oechsle (used most widely in Germany) and Baumé.

In many wine regions, producers can supplement low levels of sugar in their grapes by adding sugar or concentrated (and naturally sweet) grape juice, called *Süssreserve* in Germany. The addition of sugar is often known as chaptalization after Chaptal, one of Napoleon’s ministers who advocated (but did not invent) the technique, but it is increasingly called enrichment. Wine laws generally regulate the degree of permitted enrichment. In Burgundy, sugar may be added to raise potential alcohol by about two percent.

In addition to sugar, producers can (depending on wine law) add acid and tannins to make up for deficits in the grapes. Just as sugar is added to compensate for low sugar concentrations in cool climate regions, acidification is practiced in warm climate regions where grapes ripen well and have high levels of sugar but have low acidity. Without some correction the wines would be unbalanced. Wine laws forbid both enrichment and acidification of the same wine.

### Aging

Beyond sugar, acid, and tannin, additives are not permitted and the only nongrape flavoring comes from wood. This is generally added during the aging process in oak barrels, but in one specific case, the production of Retsina wine in Greece, pine resin is added to the must during fermentation. It gives the Retsina an aroma and taste reminiscent of turpentine or pine.

Following fermentation, wine is generally racked (drawn off any remaining solid matter) and aged. Some wines, however, are left on the lees, the dead yeast cells that fall to the bottom of vat or barrel when fermentation is complete. Perhaps the best known of these *sur lie* (“on the lees,” or sediment) wines, which often have a yeasty note to their flavors, is Muscadet *sur lie* from the Atlantic coastal region of the Loire Valley in France.

Depending on the wine and the prevailing wine law, aging before bottling can be a short process of a few weeks or as long as several years. In general, white wines are aged for shorter periods than reds, although some reds get little aging and are bottled very soon after fermentation is complete. This is the case with *primeur* or *nouveau* wines that are put on the market within months of the harvest. The best known is Beaujolais Nouveau, a light, fruity wine from southern Burgundy that is released throughout the world on the third Thursday of November each year, only two months after the grapes are picked. It now has many imitators from other wine regions throughout the world.

Other wines sold young include the *Heurigen* (literally, “the season’s”) wines of Austria, spritzzy wines that can officially be sold after November 11 of the vintage year.

But there are also wines that are sold for consumption while they are still fermenting, like Austrian *Sturm* or German *Federweiss* (“white feather” from the cloudy appearance of the still-fermenting beverage in the glass).

Such young wines are the exception, however, and most wine undergoes a period of aging for at least a couple of months to give the flavors and other properties of the wine (like acids and tannins) an opportunity to integrate. Depending on the varietal and style, wine can be aged in an inert vessel (such as a concrete or stainless vat that imparts no additional flavor to the wine) or in a wooden container that might add flavors and tannins to the wine it contains. Some varietals, such as Riesling and Sauvignon Blanc, are almost always made and aged in stainless steel. Others, such as Cabernet Sauvignon and Pinot Noir, are almost always aged in wood. Varieties like Chardonnay are aged in stainless steel or wood, depending on the style the winemaker is aiming for.

Most barrel-aged wine is kept in small 225-liter barrels called *barrisques*, whose size ensures a high ratio of wood to wine. There are, however, barrels that hold tens of thousands of liters of wine. New barrels give the greatest flavor and tannins to wine, and barrels contribute less and less with each year of use until, after about five years, they become effectively inert. The insides of barrels are “toasted” by direct flame during construction and the degree of toasting (light, medium, heavy) influences the degree to which the wood can flavor the wine.

Although barrels have been made of various kinds of wood, the most favored is oak because of the flavors it contributes and because the tightness of the grain makes oak less porous than other wood. It thus holds the wine in and keeps the air out, although wine in barrels does experience loss through evaporation and absorption, and must be topped up now and again when aged over a long period. The two principal sources of oak are France and the United States, but there is increasing use of eastern European and Russian oak, too.

The flavors oak barrels give to wine vary according to the wine itself and to the provenance, age, and toasting of the barrel. In general, American barrels are said to give sweeter, vanilla notes to wine, while French barrels contribute more savory flavors. Both may contribute toasted notes to a wine’s flavor profile.

Because of the cost of barrels, barrel aging is an expensive proposition, and producers of mass-produced wines have devised less expensive methods of giving oak flavor to their wine. One is to use oak chips, small particles of oak that are mixed into the wine and then filtered out. Some tasters believe that oak chips give the wine an oily texture. An alternative method is to age the wine in steel tanks and to suspend oak planks into it. This has some of the same effect as barrel aging, but it does not expose the wine to oak in the same ratio and nor does it bring the wine into contact with small amounts of air as barrel aging does.

Some aged wines are known as Reserve wines and in Spanish, Italian, and Greek wine law Reserve (*Riserva* or *Reserva*) wines must be aged for specified minimum periods in oak and bottle. The word “Reserve” on the labels of most countries and regions has no regulated meaning, but is generally intended to signify a premium wine that had had a longer period of aging than its non-Reserve counterparts.

### Fining and Filtering

Other processes in winemaking include fining and filtering. Fining involves clarifying and stabilizing wine by dropping into it substances like egg whites, fish bladders, or specific clay deposits. Particles adhere to these substances and fall to the bottom of the container. Solid particles may also be removed by filtering, usually by forcing the wine through paper filters. Some wines are not filtered because the process not only removes unwanted particles but can also remove some color and flavor compounds.

### Blending

Before or after barrel aging, wines may be blended. A blend may combine wines of different varieties so as to make, for example, a Cabernet Sauvignon Merlot or a Semillon Chardonnay blend. (In any declared blend, the predominant variety is stated first.) Most of the world’s great wines are blends of more than one variety. Red Bordeaux, for example, must be a blend of between two and five specific grapes, Châteauneuf-du-Pape can include up to thirteen varieties, and Australia’s premier cult wine, Penfold’s Grange, is almost all Shiraz with a little Cabernet Sauvignon. Blends are designed to create an integrated, harmonious wine that is greater than the sum of any of its constituent varieties.

Blending can also involve bringing together wines that have been aged differently. Many Chardonnays are blends of wines that have variously been aged in French and American oak, or that have been partly aged in stainless steel, partly in oak.

Aging can also take place in the bottle (bottle aging), and some Spanish and Italian wine laws regarding wines such as Rioja and Barolo require a minimum period of barrel and bottle aging before the wine can be released for sale. Most wines, however, are ready for sale as soon as they are bottled (or, in some cases, put into plastic bladders and sold as “box wine” in large formats).

### Bottling

Wine intended for long-term cellaring (*vin de garde* or “keeping wine”) is kept in bottles. Depending on the wine, it may be cellared for decades and its components will continue to integrate over the long term. Bottles should be kept on their side so that the cork does not dry out, in an environment that is, ideally, dark and with a constant temperature between 50°–57°F (10°–14°C). Over time, tiny amounts of air do get through the cork,

and it is believed that this is important to the aging process. Wines kept over the very long term (as in the libraries of wine producers) have their corks renewed about every twenty-five years.

There has been increasing concern about the rate at which corks are vulnerable to infection and contaminate the wine they are in contact with. Estimates of corked wine range from 5 to 10 percent. Producers are increasingly substituting corks (which are made from the bark of the cork tree) with synthetic stoppers and even screw caps. Such closures seem ideal for wines intended for consumption while young (the vast majority of wines), but it is thought that a wine with a synthetic stopper would not allow the air that seems crucial to proper aging.

Standard wine bottles hold three-quarters of a liter (75 cl or 750 ml) of wine, but common alternatives are half bottles (375 ml) and magnums (two-bottle size, or 1.5 liters). Magnums of premium wine generally cost a little more than twice the price of a single bottle, partly because it is believed that wine ages better in the magnum volume than in standard bottle format.

Bottle shape does not affect aging, but it can be an important part of a wine's branding or image. There are two major bottle types: the Burgundy bottle with long, sloping shoulders, and the Bordeaux with more square shoulders. Much German wine is sold in long, slender flutes, while wine from Germany's Franken region is bottled in a squat green bottle called a Bockbeutel. Beyond patterns such as these, individual producers sometimes develop bottles with distinctive shapes and colors to identify their brands.

## Appellation

Bottles are labeled so as to indicate their contents, but not all labels carry the same information because they reflect the prevailing wine law. The great majority of wine-making regions and countries have wine laws that govern such things as food safety (additives that may be used) and what must be shown on a wine label. Laws vary, sometimes radically, but almost all regulate what is broadly called appellation. The appellation is a wine-producing region whose geographical boundaries are legally defined such that only wine made from grapes grown in the region can use the name. Thus a sparkling wine can be called Champagne only if it is made from grapes from the Champagne region of France (and if it has been made according to the rest of the Champagne wine law).

The word "appellation" comes from the French practice of regulating the names of products according to where they are made. Thus a St. Emilion wine from the Bordeaux region must be made of grapes from St. Emilion, and Camembert cheese can only be made in Camembert. Through a series of agreements, European appellations have now obtained near-monopolies over

their names, such that sparkling wines made outside Champagne cannot be called Champagne. Wines made in Australia, California, and New Zealand that used to be called Burgundy or Chablis (both French appellations) have been renamed. Sherry and Port (Spanish and Portuguese appellations respectively) will eventually follow.

Many European wines are labeled only by appellation. Examples are Burgundy, Rioja, and Chianti. But because the wine laws of each appellation specify the varieties of grapes that can be grown in the regions, the appellations are a kind of coded grape variety. Thus red Burgundy can be only Pinot Noir, white Burgundy can be only Chardonnay, Rioja is mostly made from the Tempranillo variety, and Chianti is mostly Sangiovese. In most of the non-European wine world, however (and parts of Europe), wine is labeled by variety (these are varietal wines) because wine laws do not limit the kinds of grapes that can be grown. Italy is a mixture of appellation and varietal labeling, as is Spain, but most German wine is labeled by variety.

Appellation regulations take different forms in different countries. Legally defined appellations in the United States are called American Viticultural Areas (AVAs), while in Australia they are called Geographical Indications (GIs). In order to identify a wine by an AVA, such as Napa Valley, Willamette Valley or Bell Mountain, a wine must be made of grapes 75 percent from that AVA. Countries such as Australia and Canada (Ontario) require 85 percent grown in the stated wine region. In addition, wine laws require a varietal wine to be a minimum percentage of that variety. A California Chardonnay must be at least 75 percent Chardonnay and it can be up to 25 percent of the other varieties.

## Vintage and Alcohol Level

Vintage years and alcohol levels stated on labels can be equally flexible. A New Zealand wine labeled 1999 needs only be 85 percent of that vintage (there could be 15 percent of 1998 or an earlier vintage). And the alcohol level needs be only within one percentage point either way of the stated level, so that a wine labeled 12.5 percent can have between 11.5 percent and 13.5 percent alcohol. Almost all wine laws allow this kind of flexibility.

Some wine laws also differentiate among different quality levels. In Europe there are three: a basic table wine (French *vin de table*, Italian *vino di tavola*) made according to few restrictions; regional wines (like French *vin de pays* and Spanish *viño de la tierra*) made with more restriction and meant to reflect the wines of a specific region; and quality wine (French *Appellation d'Origine Contrôlée* and German *Qualitätswein*), which is the highest rank of all. In reality these are only guidelines: some table wines are of higher quality than so-called quality wines, but do not qualify for the highest rank because they use grapes not permitted by wine law for that category.

## Styles of Wines

There are many different styles of wine, allowing wine to satisfy a wide range of individual tastes and occasions, and permitting wine to accompany many styles of food. Most table wines are dry in the technical sense that they contain no residual sugar because all the sugar that was in the grapes (or added to the must) has been fermented out. Even so, wines can feel sweet in the mouth because of their fruit flavors, and many varietals like Chardonnay, Shiraz, and Zinfandel have a sweet fruit dimension to them. (Alcohol also tastes sweet, and a high alcohol level adds to the sweet sensation.)

Wine should be assessed in terms of the way all its component parts fit together. A white wine whose acidity and fruit flavors are balanced tastes better than one where there is an imbalance. Many inexpensive Chardonnays are so heavily oaked that it is difficult to detect the fruit. For many reds, it is a matter of achieving a good relationship among acidity, fruit, tannins, wood, and alcohol. Too high alcohol can ruin an otherwise good fruit-acid balance, as can too much oak.

But wines that are intended for long-term cellaring are often unbalanced when young, and the purpose of aging them is to allow time for them to integrate. Many new Bordeaux reds, for example, have such strong tannins that they are undrinkable for the first few years. But the great bulk of commercial wine is made for early drinking (within four or five years of vintage) and they are more likely to deteriorate rather than improve if kept much longer.

## Food and Wine

Matching food and wine has preoccupied wine and food writers for centuries. Rules of thumb such as “white wine with fish, red wine with meat” used to be popular, but current thinking is much more flexible. In general there are two ways of thinking about the wine-food relationship. One is to match their flavors, so that dishes high in acid are accompanied by similar wines. Thus, tomato-based dishes (tomatoes being acidic) often pair well with many Italian wines that have high acidity. The second approach is to contrast food and wine. Thus a dish with a heavy, creamy sauce would not be paired with a heavy, buttery Chardonnay but with a substantial but leaner, even crisp wine whose acidity will cut through the fat in the dish and refresh the diner’s palate.

Although there are no rigid rules for matching wine and food, useful principles are to match the weight of each and to consider the dominant flavors of the food. Just as some foods feel lighter or heavier in the mouth (compare sole and steak) so all wines fall on a spectrum of light to full bodied. Many young white wines (like Soave and Verdicchio) feel light, whereas older Semillons and Shirazes are full bodied. Matching the weight of the wine to the food creates a balance.

As for matching flavors, it is important to consider the dominant flavors in a dish. Roasted chicken with sage

stuffing, barbecued chicken, chicken marsala, and chicken tandoori all have quite different flavors because of the herbs, spices and other ingredients used in their preparation, even though chicken is common to them all. Generally it is not the meat or fish that gives a dish its main flavors, and advice to match a particular wine to fish or chicken is not very useful. Instead, it is desirable to match wine to the strength, intensity, and quality of the ingredients that provide the main flavors.

Finding a perfect match of wine and food (called a marriage) is often a matter of trial and error, but there are some classic matches. They include Sauvignon Blanc with oysters or goat cheese, full-bodied red wine with simply prepared steak or full-flavored game, and Eiswein (ice wine) with strong blue cheese. Some foods are difficult to match with wine, including dishes whose flavors are heavily influenced by vinegar or citrus juice.

Advice on wine to accompany a meal at a restaurant should be available from the sommelier or server. A sommelier (who historically was employed by a king or noble to look after the pack-animals—the *bêtes de somme*—who carried the food and wine) should have full knowledge of the way a restaurant’s dishes are prepared and should be familiar with all the wines on the wine list. He or she should know how hot or spicy a dish is and what the strongest flavors are.

A sommelier’s tasks include developing a wine list appropriate for the restaurant’s cuisine, and ensuring that the wine is properly kept and served. Once a diner has selected a bottle, it should be brought unopened to the table and presented to the diner to ensure that it is the correct one. The bottle should be opened and a small amount of the wine poured for the diner to taste. The purpose is to ensure that the wine is in good condition and not corked or flawed in any other way.

## Drinking Wine

Flaws can generally be detected by smell alone, but it is a good idea to taste the wine, too, if only to check its temperature. White wines are often served too cold and reds too warm. There are no hard-and-fast rules about serving temperature, but white wines should not be so cold that they have no taste or so warm that they lose their feel of fresh acidity. And although it is a rule of thumb that red wine should be served at room temperature, many modern rooms are so warm that wine served at their temperature taste coarse and alcoholic. Although there is commonly a difference of about 15 degrees in the serving temperature of whites (wine straight from a refrigerator is about 39–43°F [4–6°C]) and reds (rooms are commonly 68°F [20°C] and warmer), the difference between them should be much narrower. In broad terms, white wine can be served at ideal cellar temperature (about 53°F [12°C]), while most reds do well at about 60–64°F (16–18°C), a difference of only four to six degrees.

Although many people insist on opening wine an hour or two before serving so that it can breathe, experiments show that merely removing the cork makes little difference to the taste or quality of the wine. Exposing some wines to air can improve and soften them, but this is best done by decanting the wine beforehand or simply swirling it in the glass. Special care should be taken with very old wines, which can begin to degrade very soon after they are opened.

The size and shape of the glass can make a difference to the experience of a wine. There are now glasses designed for every varietal and style of wine by companies such as Riedel. For ordinary use, the most satisfactory glasses have a mouth smaller than the widest point of the bowl, so that the aromas are trapped. The stem should be long enough that the glass can be held comfortably by it; holding a wineglass by the bowl can warm the wine and dirty the bowl.

### Health Benefits

Beyond the sheer pleasure that wine can give, it appears to have health benefits if consumed in moderation. Historically, wine has been attributed myriad therapeutic properties, but for much of the twentieth century the stress was on its toxic properties and its ability to inebriate consumers. The discovery of the “French Paradox” revived interest in the relationship between wine and health. The paradox is that, given their level of wine consumption, the French ought to have a higher rate of heart disease than they do. An explanation was that wine actually protected against coronary disease. The weight of current research supports that conclusion, but doctors stress that it applies only to moderate consumption: about one or two glasses a day by men, one glass by women. More than that neutralizes the health benefits.

There are many guidelines for the maximum enjoyment of wine but, in the end, each individual finds the relationship with wine that she or he is comfortable with. Individuals have different taste preferences and varying tolerance of tannins and acids. Food and wine pairings that repel some, delight others. The great thing is that wine, the result of the complex interplay of work by countless humans and a seemingly infinite combination of natural circumstances, comes in such a wide range of styles that there is a wine to please everyone, to match any dish, and to suit any occasion.

### WINE IN THE ANCIENT WORLD

The earliest evidence of wine dates to about 5000 B.C.E. in the Middle East, where archaeologists have discovered earthenware jars and other vessels containing grape seeds and stems. Others contain deposits of tartaric acid and calcium tartrate that are almost certainly the residue of grape liquid because grapes are rare among fruit in that they accumulate tartaric acid. Any grape juice not consumed very quickly would have soon fermented into wine in the warm temperatures of the region.

The earliest known wine jar (dated to 5000 B.C.E.) was found in the Zagros Mountains of modern western Iran. Excavations elsewhere in the region located 30- and 60-liter (7.92- and 15.85-gallon) earthenware jars, all with wine deposits, dating from 3500 to 3000 B.C.E. Similar evidence of wine-making at this time has been found at many locations in the Fertile Crescent (the region south of the Caspian and Black Seas and including parts of modern Turkey, Armenia, Georgia, and Iran).

Many scholars speculate that the first vintage was an accident, the result of fresh wild grapes being crushed accidentally and fermenting spontaneously. Over time, people began to crush the grapes deliberately and also began to select and cultivate varieties that produced better wine (such as grapes with a high pulp-to-pip ratio).

Many ancient accounts of the origin of wine stress its accidental character. One refers to the Persian king Jamsheed, who was so fond of grapes that he stored them in jars so as to have supplies out of season. When one lot

Wine shops were common throughout the Roman Empire. This bas-relief from the Museo Nacional de Arte Romano shows a shop owner pouring wine into a carafe in much the same way as beer is kept on tap today. © ARCHIVO ICONOGRAFICO, S.A./CORBIS.

fermented, he thought they had gone bad, and had the jar labeled “poison.” When a woman from his harem, suffering headaches so bad that she wanted to die, drank the wine with the intention of killing herself, she fell asleep under the effect of alcohol. When she awoke, her headache was gone, and thus was born wine and its ancient reputation as a medicine.

Wine played a part in the diet and culture of all ancient societies from the Neolithic period onward. For the most part, it was a privileged beverage of the elites, while beer was the drink of the masses. A relief from seventh-century-B.C.E. Nineveh shows King Assurbanipal and his queen resting under a trellis of vines and drinking wine from cups. In Nimrud, a ration of wine was given to all six thousand members of the royal household. The basic male ration was 1.8 liters (3.81 pints) for ten men each day, while skilled laborers got twice that. The queen and her retinue received 54 liters (14.26 gallons) a day, but we do not know how many individuals shared it.

One reason for the special status of wine was its scarcity. Grain grew far more widely and easily than grapes, and beer (really liquid bread) could be made year-round as long as grain was available. But grapes grew only in certain localities and ripened only once a year, so that

there was limited scope for wine-making. Moreover, each year’s wine had to last a year, until the next vintage was ready for drinking. In regions where grapes did not grow, wine had to be imported, thus adding to its cost.

One of the earliest wine trade routes ran a thousand miles down the Tigris and Euphrates rivers from the vine-clad mountains of northern Mesopotamia to southern Mesopotamian cities like Ur, Babylon, and Sumer. This trade route lasted for thousands of years, and it appears that many regions began by importing wine and then proceeded to cultivate grapes and make their own wine. There is clear but uneven evidence of viticulture and wine making from 5000 to 3000 B.C.E., but they probably spread in a number of directions from the Fertile Crescent, one track taking them to the eastern seaboard of the Mediterranean and then south toward Egypt. The Middle Eastern climate around 3000 B.C.E. seems to have been wetter than today, allowing for cultivation in regions where it is no longer possible.

Egypt provides the most coherent image of an ancient wine culture. Hundreds of clay jars of wine (with a total volume of some 4,500 liters (118.78 gallons) were buried with one of the first Egyptian kings, Scorpion I (about 3150 B.C.E.). Analysis of the clay shows that the jars were made in the modern Israel-Palestine region.

Between 3000 and 2500 B.C.E., Egyptians began to grow their own grapes, mainly in the Nile Delta (where the earth was fertile and the heat was moderated by the Mediterranean), but also further south. The vines were owned by royalty and great officials and by priests, and a census taken about 1000 B.C.E. listed 513 vineyards owned by temples alone throughout the country.

Vines were often trained on trellises, irrigated, and fertilized with pigeon droppings. Wall paintings show the wine-making process in great detail. The grapes (almost always depicted as black) were trod by slaves in a vat and the juice was run off into fermenting jars. The must (unfermented juice) is usually colored red or black, which suggests there might have been some period of skin contact. The residual skins and other solids were squeezed in a sack to extract every drop of juice.

Fermentation took place in large clay jars that were sealed, apart from a small hole that allowed the carbon dioxide to escape. Each jar was identified with a clay seal, the forerunner of the label, that might give information on the year, the vineyard and the name of the wine-maker.

The aroma, taste and texture of Egyptian wines are lost to us, but in any case the wine was often flavored with herbs and spices before being consumed. But they cannot have been very stable because the grapes were picked and crushed in August, were slowly crushed and pressed and then rapidly fermented, all in the summer heat. Moreover, the clay jars were slightly porous (unless they were coated with resin or oil), which would have led to a degree of oxidation. There was no premium on ag-

ing wine here, and there are records of wine going bad after twelve to eighteen months.

Wine cost about five times more than beer, the staple beverage of the Egyptian masses. It was consumed by powerful and wealthy individuals and by priests attached to temples that owned vineyards, who received wine as part of their salary. The elite status of wine is indicated by its prominence in the burial chambers of the kings. Thirty-six jars of wine were buried with the young King Tutankhamen.

Wine played an important role in Egyptian religion, as it did in religions in other parts of the ancient world, and it was poured as a libation or offering to the gods as prayers were said. Ramses III claimed to have presented 59,588 jars of wine to the god Ramon-Re. Some texts present wine as divine in origin: as the perspiration of Re, the sun god, or as the eyes of the god Horus. Wine was also used for medical purposes. Physicians prescribed it to increase the appetite, purge the body of worms, and treat asthma. It could also be applied externally to bring down swelling and to treat wounds.

By the time wine reached Egypt it had come to occupy a privileged place in the diet and culture of the elites. It is possible that viticulture was transferred from Egypt to Crete and from there to the European mainland. The ancient world thus established practices and attitudes that were adopted and adapted by later societies.

### WINE FROM CLASSICAL TIMES TO THE NINETEENTH CENTURY

In the more than two thousand years between the Classical period and the nineteenth century, wine underwent changes in almost every respect. The geographical extent of viticulture (the cultivation of grapes), vine cultivation, wine making, trade, and the culture of wine consumption were all transformed as part of broader political, social, economic, and cultural transformations.

### Wine-Making in Ancient Greece

The beginnings of wine-making in Greece by about 1000 B.C.E. were an important step in the history of wine. Until that point, wine had been a marginal product, made in relatively small volumes and consumed only by social elites. This had been the case in ancient societies like Mesopotamia and Egypt. In Greece, however, vineyards expanded rapidly from their initial sites near main population centers and markets to more distant islands like Thasos, Lesbos, and Chios, and by the third century B.C.E. there was a veritable wine industry in the region.

Wine was consumed at all levels of society and it became, along with oil and grain, one of the three main products of Mediterranean agriculture and commerce. Greek wine could be found in locations as diverse as France, Egypt, around the Black Sea, and in the Danube region. Moreover, the Greeks introduced viticulture to France (with limited plantings near modern Marseilles), southern Italy, and Sicily.

The extent of the Greek wine trade is evident in the many wrecked ships along the Mediterranean coast. One ship carried an astonishing ten thousand amphoras (six-to seven-gallon earthenware jars) that would have contained as much as 66,000 gallons of wine, or 400,000 standard modern bottles. It is estimated that 2.2 million gallons of Greek wine were shipped to France each year through the port that is now Marseilles.

The Greeks not only supplied foreign markets with wine, but they also consumed vast quantities domestically. Far from being an elite beverage, wine was consumed at all levels of society. This was an example of an egalitarian approach to drinking expressed by Euripides, who wrote that Dionysus (the Greek god of wine) had given "the simple gift of wine, the gladness of the grape" to "rich and poor" alike. Yet there were significant variations in the quantity and quality of wine consumed at different social levels. The affluent drank wine that was described as quite full-bodied and sweet. The poor drank a thin, low-alcohol, bitter solution made by soaking the skins, seeds, and stalks left over after the final pressing of the grapes.

Greek males of the upper social strata developed a specific institution for consuming wine: the symposium, meaning "drinking together." A dozen or more men, all wearing garlands on their heads, reclined on couches and drank diluted wine while conversing, being entertained by young men and women, and playing games that often involved wine. Symposia were idealized as occasions for elevated discussion and cultural activities, but often they were merely boisterous drinking sessions. Greek wine cups were often decorated with scenes of drunkenness and sexual activities at symposia.

Women were excluded from symposia (except as servers, entertainers, and prostitutes) and there is evidence in Greek writings of male anxiety about women drinking wine. Women were believed to become intoxicated more

quickly than men and to behave immorally once in that state. These became persistent themes in Western culture, and they underpinned lower consumption rates of all forms of alcohol by women.

Although it was apparently a not uncommon occurrence in symposia, drunkenness was generally frowned upon in ancient Greece. Homer highlighted the dangers of drunkenness in the *Odyssey*, in which several characters meet their deaths in accidents caused by drunken men. Yet moderate consumption of wine was viewed as beneficial. Hippocrates, regarded as the founder of Western medicine, wrote extensively on the effects of different types of wine on the digestion. He criticized “dark and harsh” wines as difficult for the body to digest and expel, but praised “soft dark wines . . . they are flatulent and pass better by stool.”

As for wine production, the Greeks paid serious attention to viticulture and wine-making. They adopted techniques of growing vines along trellises and up stakes to make the grapes more accessible during harvest. Vinedressers, who were responsible for the vital pruning operations in the vineyard, became a recognized profession. It was the Romans, however, whose empire superseded that of the Greeks, and it was they who left the most coherent documentation on wine in the Classical period.

### **Wine-Making in Ancient Rome**

A host of writers, including Cicero, Pliny, and Cato, described viticultural and wine-making practices in Rome and wrote extensively about the wines available to them in the last centuries B.C.E. In about 65 C.E., Columella described the principles of viticulture, including the recommended density of vines, the importance of selecting appropriate sites for vineyards, and the economics of vine-growing. For his part, Cato stressed the importance of sunlight to grape-ripening and outlined the basic principles of canopy management.

Roman writers also focused on wine-making and gave recipes for wines that would appeal to Roman tastes. Unlike modern wine-making methods, where additives are minimal, Roman wine was a grape-based concoction that might include sea-water, honey, and all kinds of herbs and spices. Additional flavors might be contributed by the pitch and resin sometimes used to seal the insides of earthenware jars, and sweetness could be added by boiling the grape juice in a lead vessel. Lead not only sweetened wine, but it also preserved it by killing some bacteria. (Lead’s potential toxicity was recognized but was largely ignored until the seventeenth century.)

Roman wine writers paid attention to the quality of wines. They gave particular value to color, body, and sweetness, but they also noted wines that they believed had special medical properties. Athenaeus praised wines from Alexandria, which he thought were excellent, fragrant, not likely to go to the head, and which had diuretic effects. Strabo gave high marks to wines from

Turkey and Aegean islands like Cos, Chios, and Lesbos. In the first century C.E., Pliny the Elder provided a catalogue of wines from various parts of the empire: ninety-one varieties of wine, fifty kinds of quality wine, and thirty-eight varieties of foreign wine. His list is notable for its stress on varieties rather than just provenance.

The engine of the Roman wine industry was Rome itself, which grew from 300,000 to over one million inhabitants between 300 B.C.E. and the beginning of the first century C.E. By that time, Romans were consuming an estimated 39.6 million gallons of wine a year, which was about seventeen fluid ounces a day for every inhabitant. Not only did the region around Rome provide this wine, but many other parts of the Italian peninsula shipped it as well.

The prominence of wine in the Roman diet was threatened when Mount Vesuvius erupted in 79 C.E., burying the wine port of Pompeii and destroying many vineyards and two vintages of wine (one in warehouses, the other still on the vines). The immediate shortage of wine led to such a rush to plant new vineyards that there was a glut several years later. The Emperor Domitian tried unsuccessfully to limit the land under viticulture in Italy and to reduce vineyards in Rome’s overseas provinces such as Gaul. The ostensible reason for the policy was that vineyards were taking over land needed for grain production, but it is thought that Domitian was as much concerned with protecting Roman wine producers from competition.

Despite any pressure there might have been from wine producers in Italy who wanted to protect their export business, the Romans extended viticulture throughout Europe as their empire expanded. By the first century C.E., most of the famous French wine regions (including Bordeaux, the Rhône, and Burgundy) had been planted, as had areas in England, Germany, Hungary, and other parts of southeastern Europe. The Romans were thus responsible for the beginnings of the European wine industry.

As was the case in Greece, Rome’s wine culture was generally inclusive, and everyone from the elites to slaves consumed wine. Cato proposed that slaves in chains should receive about 1.3 gallons of wine a week—not for pleasure but to give them strength to work. (The ration allotted to a sick slave was half that of a healthy, working slave.) Also as in Greece, in Rome there were vast differences in the quality of the wine consumed by different social groups.

In Rome there was also concern about wine consumption by women. One myth told of a husband who beat his wife to death with a stick for drinking wine, a punishment said to have been praised by Romulus, one of Rome’s founders. For a brief time, Roman law allowed a man to divorce his wife for drinking wine, and women were associated with the cults centered on Bacchus, the Roman god of wine. The authorities concocted stories of

wild, drunken orgies (Bacchanalia) in order to suppress the cults, which had become implicated in opposition to the government.

Drunkenness, whether on the part of women or men, was broadly condemned by Roman commentators. Cicero frequently labeled his opponents drunkards and alleged that his main rival, Mark Antony, started drinking early each morning. Others cautioned against excessive drinking for a variety of physical and mental reasons. Lucretius argued that wine could disturb the soul and weaken the body, while Seneca wrote that wine revealed and magnified character defects. Pliny the Elder praised quality wines, but he warned that many of the truths spoken under the influence of wine were better not expressed.

On the other hand, Classical medical opinion generally held that wine, alone or with other substances, had curative properties, particularly for gastric and urological ailments. Cato recommended certain flowers soaked in wine as effective for snakebite, constipation, gout, indigestion, and diarrhea.

If wine had achieved a privileged status at the center of the Roman Empire, some non-Roman populations on the margins of Roman control carved out their own relationship with the beverage. For Jews, wine was a powerful expression of divine power. When Moses sent out scouts to survey the Promised Land, they returned with a bunch of grapes so massive that it took two men to carry it. Grapes and wine were such important signs of the bounty provided by God to the Jews that the Old Testament frequently threatens that God will make the vines barren if Jews disobey God's word.

This intense symbolism of wine carried over to Christianity. The first miracle performed by Christ was to turn water to wine at the wedding at Cana. Wine became an integral part of Christian theology, ritual, and tradition. In the Christian sacrament of the Eucharist, wine represents the blood of Christ, and there are many representations of "Christ in the wine press," where Christ's blood, flowing from wounds inflicted during the crucifixion, mixes with the red juice flowing from the grapes as they are crushed.

Because the Eucharist required wine, Christianity and wine became so intimately connected that in the first centuries C.E., conversion from beer to wine became a sign of conversion from paganism to the new religion. Many religious houses had their own vineyards. Monasteries were centers of learning, not only in theology but also in the practical sciences, and for hundreds of years religious orders were at the forefront in developing new techniques in viticulture and wine-making.

### **Wine-Making in the Middle Ages**

The invasion of the western region of the Roman Empire by tribes from central and eastern Europe from the fifth century C.E. did not affect European viticulture as

dramatically as once thought. It is possible that some vineyards were abandoned, but overall it seems that Europe's new rulers were as interested in protecting viticulture as the Romans had been. What did suffer was the wine trade, as the single Roman Empire was broken up into smaller political units, each dominated by one of the invading tribes.

It is a mistake, then, to think of a Dark Ages of wine, and certainly misleading to suggest, as some scholars have done, that viticulture survived only because of the vineyards owned by the Christian Church and various religious houses. They were undoubtedly important and some were extensive: the Abbey of St.-Germain-des-Prés near Paris had 1–1.5 square miles of vineyards in 814 C.E. The Church also sponsored the expansion of vineyards in the important Rhine region and in Austria and Switzerland. Even so, many vineyards had secular owners, and viticulture and wine was not particularly threatened in this period. However, with a decline in trade, many regions began to cultivate their own grapes.

The real threat to wine (and alcoholic beverages generally) emerged not in Europe, but in the Middle East, the birthplace of wine. There the Islamic religion took hold in the seventh century, and within a hundred years it had extended its control across northern Africa, the Iberian Peninsula, and, for a short time, parts of southwestern France. The Prophet Muhammad forbade his followers the consumption of alcohol. Although he acknowledged that wine could make people happy and sociable, he believed that its threats to social order and morality were so great that alcohol should be banned. Wine production practically dried up in many parts of the Islamic empire, but in some parts (like Spain) it was generally tolerated and even acknowledged in so far as it was taxed by Muslim authorities.

Wine production and trade in Christian Europe began to boom around the year 1000 C.E. One reason was the creation of a large political unit in Europe under the Emperor Charlemagne. This not only encouraged commerce, but Charlemagne himself encouraged wine production. He is said to have given the hill of Corton (in Burgundy) to the Abbey of Saulieu; the wines from this estate are known as Corton-Charlemagne.

A further reason for the expansion of wine production from 1000 was the growth of population, cities, and trade that took place in Europe between 1000 and 1300. In northern Europe, northern Italy, and elsewhere, new urban middle classes of entrepreneurs and merchants emerged, all with a thirst for wine. Wine regions close to these new urban markets (like those in Tuscany and other regions of northern Italy) prospered. However, many of the new cities were in areas unsuitable for viticulture, and wine trade routes developed to serve them. Among the most important were the sea route from southwestern France (now the Bordeaux region) to England and the northern European ports, and the wine trade

# Ein Schönsbuch

down the Rhine River from the vineyards of central and southern Germany to the North Sea and Baltic ports.

This boom period for the medieval wine industry ended with the Black Death that struck Europe from the mid-fourteenth century. The European population declined by as much as a third, and as markets contracted and vineyard workers died or fled the plague, many vineyards were abandoned. Production and trade began to recover as population and markets grew again in the sixteenth century. There were slight setbacks in this period, when religious reformers like Calvin and Luther accused the Church of Rome of being morally lax, including being tolerant of drunkenness. The Protestant religions tended to be hostile to social drinking, and it is interesting that the only European wine region to become Protestant was Switzerland.

## Wine-Making Advancements and Expansion

During the sixteenth to the nineteenth centuries, there were many varied developments in viticulture and wine-making. Lead was abandoned as a means of sweetening wine, and adding sugar to raise the alcohol level of wine became a common practice. (It was later known as chaptalization, after Napoleon's minister of the interior, Chaptal, who recommended it to compensate for grapes that did not ripen fully.)

New styles of wine emerged, too. The technique of making sparkling wine evolved, and bottles and stoppers developed so that it could be conserved more reliably. Starting in the late seventeenth century there was increasing recognition of the individuality of wines from specific estates. The first wine to be marketed as an estate wine was Haut Brion from Bordeaux, which appeared on the London market in the 1660s.

Wine was, in this period, part of the daily diet in many parts of Europe. Reliable statistics on per capita consumption are hard to come by (because the information was not collected) but common estimates range from 17–101 fluid ounces a day. The impact of these volumes depends on the alcohol content of the wine, which was often diluted with water.

Wine was also part of some people's income or entitlement. Artisans employed by the Duke of Lorraine received an allotment of wine as part of their daily wages, and wine was a standard element in military rations. In 1406, the six men who guarded the Château de Custines each received two liters of wine a day.

It was during this period, too, that Europeans extended viticulture beyond Europe itself. The first major advance was the invasion of Central and South America by Spain in the sixteenth century. Vines were planted in Mexico in the 1520s, and viticulture rapidly spread down the west coast of South America in the wake of the invading Spanish armies and Jesuit missionaries. As mission stations were established, vineyards were planted, and the connection was so strong that the grape commonly planted became known as the Mission variety. By the 1550s, major vineyards had been established in Peru, Chile, and Argentina. During the 1600s, the Dutch established vineyards in what is now South Africa, and in 1788 the first vines were planted in Australia.

Viticulture in North America was far less successful. Settlers tried to make wine from native grapes from the 1600s and later tried unsuccessfully to grow European varieties. A combination of climate and disease condemned most of these attempts to failure, and even though Franciscan missionaries established vineyards in California in the eighteenth century, it was not until the nineteenth century that wine was produced in America in meaningful volumes.

The nineteenth century was a turning point for wine, in many respects. From the 1860s onwards, vineyards throughout Europe and other parts of the world were

devastated by a North American aphid called *Phylloxera vastatrix*. Unable to eradicate the pest, vine-growers began to graft their vines onto the roots of native American vines that were tolerant of the aphid. The *Phylloxera* disaster affected European wine production for several decades, but it gave a boost to production elsewhere. California vineyards, which had expanded after the end of the Gold Rush, grew rapidly as producers eyed the disaster in Europe and imagined California taking over the world wine market.

The advent of the railroad was a boon to production in many countries. It made eastern markets available to California wine and enabled producers in the south of France to get their inexpensive wine to France's northern industrial cities.

At this same time, a wave of anti-alcohol sentiment swept across many countries. Temperance and abstinence movements had varying success in having alcohol laws tightened, and some American states introduced Prohibition. These movements were reinforced by the discovery (some scholars refer to it as the construction) of alcoholism in the mid-nineteenth century, which seemed to confirm the dangers of drinking any alcohol, including wine.

During the two millennia that separated the Classical period from the end of the nineteenth century, wine had changed from being an elite beverage to one shared by all sectors of many societies. It had spread globally, and it had sensitively reflected broad shifts in economies, societies, and culture. There were also continuities. Voices across this long period spoke to the dangers of excessive drinking, and others praised the health benefits of wine. The experience of wine in this period confirms the importance of understanding wine in its historical and cultural contexts.

## WINE IN THE MODERN WORLD

At the start of the twentieth century wine was a beverage with a very limited range. Essentially it was made as a bulk product by peasants in southern Europe and was consumed by all classes in the country of origin. A small amount of premium wine found its way to the tables of the rich in the capital cities of Europe and the European diaspora. Some outposts of production existed in the United States and the colonies of Europe, but they were insignificant both qualitatively and quantitatively. The Bordeaux vintage of 1900 was highly regarded, but the production and consumption of that style of wine was marginal to the substantive function of the drink.

### The Years of Decline

Despite the great opening vintage, the first decades of the century were not happy ones for wine producers. By 1900 phylloxera had completed its devastation of the European viticultural landscape, often leaving vineyards replanted with low-quality hybrid vines that brought viral disease in their wake. Algeria was widely planted and produced large amounts of cheap *vin ordinaire* (ordinary wine). Agricultural depression and the flight of the population to the cities exacerbated the situation; then came World War I. Meanwhile, for the producers of prestige wines a continual flood of impostors from poor-quality viticultural regions seeking to gain the premium offered by reputation devalued that reputation and reduced their profits.

The response was to define a system that, it was argued, would protect both the producer and the consumer. By defining the boundaries of a given region and allowing only wine from grapes grown there to carry the name of the region, producers could maintain a price premium, and consumers could have certainty about the nature (and by extension the quality) of what they were drinking. The first nationwide appellation system was developed in Portugal, but it was perfected in France from 1935 onward in the *appellation contrôlée* system with the legal enshrinement of the definitions of "quality wine" and "table wine."

This codification of a classification system helped producers in prestigious regions but did little for the bulk producers, still almost all agricultural peasantry with little capital to invest in the technical advances in the winery. In these regions a strange combination of corporatist government and anarcho-syndicalism produced wine cooperatives that were controlled by local small-scale grape growers and to which they could sell their produce. Cooperatives in turn could raise the necessary capital to invest in production facilities.

### The Technological Revolution

The development of both the science of biochemistry and the technology of agricultural engineering started a revolution in wine production that expanded even more rapidly after World War II. Originating in the work of Louis Pasteur in the second half of the nineteenth century, enology

A visitor to the Robert Mondavi Winery in Napa, California, attends a weekly class on wine tasting. Wine tastings have become an important tool for educating the public about wine and its different aromas and flavors. © CHARLES O'REAR/CORBIS.

and viticulture developed a rational, scientific base. It was no longer enough to continue practices merely because they had been adopted by one's forebears. Universities like Bordeaux and Montpellier in France and later the University of California at Davis and Adelaide in Australia began both to research wine and to teach those who would grow grapes and make wine. As the science developed, so did the wines. Control of yeast and bacteria meant that off-dry and medium-dry wines could be safely marketed. This allowed massive expansion of styles like German *liebfraumilch*, which dominated the white wine market in the United Kingdom until the 1980s. This technological change came late to wine, perhaps because it was an agricultural, often peasant-based product, but it became crucial as, with the development of the railways and the new markets of industrialized nations, wine had to travel some distance and had to remain stable enough to be drinkable.

Technical development involved three key areas. First was the understanding of the importance of anaerobic handling, the need to control oxygen contact both to preserve fruitiness in wine and to avoid bacterial spoilage. Second was the recognition of the significance of hygiene during wine making and handling, again to avoid spoilage. Underpinning both of these was an increased control of all stages of the process: temperature control, specially cultured yeasts, prepared bacteria to stimulate the malolactic fermentation, and the addition of enzymes that enhance the development of "natural" aromas in the wine (such as pectinase and apiosidase). A

modern winery could be a tank farm with a central computerized control room that monitored what each batch of wine was doing.

Viticulture developed at the same time. Spurred originally by the need to combat phylloxera, then by the requirements of rapid new plantings in the Americas and Australasia, pest control, soil management, irrigation, and controlling the canopy of the vine to maximize sun exposure have been led by science. The result has been to raise the quality of the most basic wines, so even at the cheapest end of the market the consumer can expect to get a fruity, fault-free wine rather than one dominated by oxidative flavors and coarse tannins. The converse, some critics claim, has been to make wines more homogeneous. This, they argue, means that wines have lost their personalities, and wines from across the world increasingly resemble each other. Certain wine makers have reacted against such a clinical approach to let the wine develop in its own way. But even when producers indulge in so-called "dirty wine making" in pursuit of individuality, they do it from a position of knowledge, not faith, as their predecessors would have done.

### A New World of Wine

At the start of the twentieth century the production of wine was firmly European. This was not so by the start of the twenty-first century. Although France, Italy, and Spain still dominated in quantitative terms, together producing over 50 percent of all the world's wine, their international reputations increasingly were challenged by

the “new producing” countries, those of the New World. In the U.K. market, something of a yardstick, Australia became the second most popular country of origin after France.

This growing international reputation for the new producing countries reflected a rapid increase in their production. Consumption in the wine producing countries of Europe dropped dramatically, and at the same time national governments and the European Union pursued policies designed to reduce production, particularly in the bulk wine producing regions around the Mediterranean. In the new producing countries the reverse was true. From a low base, consumption rose, but production of wine grapes rose even more dramatically, driven not just by domestic demand but by the desire to penetrate new markets in northern Europe, North America, and eastern Asia.

The newer wine producing countries have been at the forefront of structural changes in the industry. In the early twenty-first century Australia had over 56,000 grape growers, each with an average holding of 1.25 hectares (3 acres), making the industry highly fragmented. In New Zealand, the most concentrated of all producing nations at that time, the largest company (Montana) was responsible for over 60 percent of all wine made. The California producer E. & J. Gallo made more wine in a year than the whole of Australia or the whole of the Bordeaux region. This does not mean that Europe does not have large companies. At the beginning of the twenty-first century the French-based Louis Vuitton Moët-Hennessy produced more wine each year than any other company in the world. Nevertheless, Europe does have a more fragmented industry.

Wine production in the new producing countries tends to be dependent on access to capital rather than inheritance. This has had another consequence, for access to capital facilitates greater use of the equipment modern technology offers. The focus on control and hygiene mentioned above is particularly significant—some would say obsessively so—in these countries. Again it is not true that wine producers in Europe disdain technology, as some in the erstwhile colonies would claim. Some Bordeaux châteaux have state-of-the-art equipment, and the *champenois* (people of Champagne) are world leaders in the production of sparkling wine. Crucially, however, fragmentation makes widespread access both to the technology and the attitudes that accompany it less likely.

### Changing Market

As the geography of production has changed, so has the geography of consumption. Changes in income patterns, reflected in the development of consumer culture, as well as travel, both voluntarily with holidays and forced in migration or war service, have made wine more accessible to many. Technology allows better wine to be made cheaper, and the blurring of class difference means wine is perceived less as the drink of the elite in many coun-

FIGURE 1

tries. A nascent wine culture in East Asia has offered the world's producers yet more opportunity to sell their wares and, with that region's focus on the label as a status symbol, has generated a rapid escalation in price of the world's most prestigious wines.

### Wine in Society

While the consumption of wine has spread widely, so too have the forces opposed to it multiplied. Historically, opposition to wine was limited to the religion of Islam. Before about 1800, moderate consumption of alcohol was almost universally accepted in western Europe, although the religious maintained that drinking to excess was wrong. However, two social movements combined to change that widespread tolerance. The social anomie of industrialization and the shift to the city resulted in widespread abuse by the poorer classes. At the same time a new religious conservatism, allied to socially concerned evangelicalism, saw in alcohol the work of the devil. Temperance is a misnomer. It means restraint rather than prohibition, but the temperance movements came to work for prohibition. The movements were most successful in the United States with the passing of the Eighteenth Amendment to the Constitution in 1919. But the impact of temperance movements was felt in strict limits on alcohol use in places as diverse as New Zealand, Wales, Canada, and Scandinavia.

Formal prohibition failed, but its influence lived on in a neoprohibitionist approach, mainly in North America and to a certain extent in Scandinavia. Justifiable concern about the effects of driving under the influence of

Viticulture continues to spread outside the traditional wine growing regions. It has become a major source of agricultural income for South Africa. This vineyard is located on the Cape Peninsula.  
© LANZ VON HORSTEN; GALLO IMAGES/CORBIS.

alcohol is confused with an absolute need to protect people from themselves and to deny them the possibility of moderate enjoyment of wine.

At the end of the twentieth century, however, another factor came in into play, the relationship between wine and health. While abuse of alcohol contributes to a range of diseases, most notably cirrhosis, science has rediscovered what doctors have known down the centuries, that moderate consumption of wine can have positive health effects. Scientists have also provided the objective evidence for this, for instance, showing the impact red wine can have on improving the balance the beneficial high-density lipoprotein component of cholesterol in the vascular system. This change in outlook was typified by the broadcasting of "The French Paradox" on television in the United States in 1991. Sales of red wine jumped dramatically overnight, followed by a prolonged battle between the wine industry and the Bureau of Alcohol, Tobacco, and Firearms about the health labeling on bottles of wine.

### The Twenty-first Century

What does the twenty-first century hold for the wine industry and the wine consumer? The pace of technological change is increasing. Disputes have developed over gene modification and the possibility of creating new varieties in the laboratory. Perhaps ultimately great wines will be recreated in test tubes. The mass production of 1961 Chateau Lafitte would horrify some but could please many.

The geography of production continues to change. The quality of wine produced in southern Europe has improved gradually, but many poor-quality sites have been abandoned because of a lack of markets for the wines. Meanwhile, as long as demand in the English-speaking and East Asian countries rises, the new producing countries will probably continue to raise their production. However, in the short term it is possible that they will suffer a glut of grapes for which no market exists. Then what happens when China begins to select appropriate sites for the production of high-quality wine?

Historically wines were sold on the basis of their geographic origins. Increasingly they are sold by the variety of grape used, and it seems likely that this trend will continue. Chardonnay and cabernet sauvignon currently dominate worldwide, but previously sherry and lambrusco reigned. The balance could yet shift to, for example, nebbiolo and manseng.

The current catchphrase is, people drink less but better. That probably hides the true shift in consumption, but it is a useful rule of thumb for how consumption changes. Critically in the late twentieth century, wine, like every other production industry, was taken over by marketing. That is not necessarily a bad thing, as part of the marketing manager's job is to ensure that consumers are satisfied with what they get. If that means more palatable wine, then consumers benefit. On the other hand, the tendency of marketing to "segment" its customers into large groups means that those who seek the unusual or the different may find it increasingly hard to find the

grape variety or region of their choice in price-point driven supermarkets that command up to three-quarters of the retail market in many Western countries. The signs, however, indicate that the gradual shift back is to greater diversity.

### WINE, NONGRAPE

Winemaking is one of the most ancient of human endeavors. Archaeological evidence suggests that early winemakers began practicing their art nearly eight thousand years ago. Since then, efforts have been largely directed toward controlling the fermentation of the grape. United States regulatory agencies classify nongrape wines by their primary component into apple or pear, fruit or berry, citrus and agricultural wine. The latter includes wines made from honey, root crops, flower parts, cacti, and rice.

Successful fermentation of nongrape materials presents a variety of challenges. Most important is increasing the sugar content in the fruit or other component. At optimal maturity of any fruit, the sugar content is insufficient to yield a wine of 10+ percent alcohol. As a result, winemakers are allowed to add sugar, a process called chaptalization. A winemaker also needs to control acidity since fruit and vegetables are often deficient. The deficiency is corrected by addition of either citric or malic acids or by blending higher acid fruit or wine. In contrast, citrus and some berries may be too high in acidity,

a defect that can be corrected by the practice of amelioration or regulated addition of water. Nitrogen deficiencies may arise from the fruit and/or processing and, if critically low, result in interrupted or stuck fermentation. Such fermentations require addition of exogenous nitrogen, typically in the form of diammonium phosphate (DAP). With the exception of berries, processing of fruit and vegetable products generally results in very poor juice yields. Pectinase enzyme preparations may be used to attack cell wall structure, liberating fluid. Alternatively, the fruit may be frozen and thawed before processing. Formation of ice crystals ruptures cell walls, which then release fluid and increase juice yield. However, this may result in premature oxidation and diminished fruit character. An alternative, fermentation of macerated pulp, rather than of expressed juice, will trap heat of fermentation and increase the probability of stuck fermentation. In contrast, fermentation of larger volumes of juice requires cooling capable of dissipating heat.

When making mead or honey wine, the principal component, honey, is typically 70 percent sugar or more, with the compositional balance reflecting type and origin of the flowers. Honeys may range in color and flavor from light, mild, and fragrant to darker and more strongly flavored. Since refined honeys have reduced character, due to thermal processing, mead producers prefer to purchase unprocessed or minimally processed honey. While intensified in flavor and aromatics, natural honey is prone to crystallization when stored at refrigeration temperatures. Although sensorially unapparent, honey is acidic (average pH 3.9). The primary acid is gluconic (5.7 g/L) with lower concentrations of other common acids, which reflect the honey's origins.

Pulque is fermented from the sap (*aguamiel*) of the Agave (Maguey), a succulent plant indigenous to the desert highlands of central Mexico. Bacteria, primarily *Zymomonas mobilis*, and yeasts have historically been responsible for alcoholic fermentation; however, modern producers use commercial yeast (*Saccharomyces cerevisiae*). Wine made from melons is not as successful as those made from other products. Unless cofermented or blended with more highly flavored fruits, melon wines are generally insipid. Further, color is colloidal: A variety of melon that is red when fermenting will become straw-yellow upon clarification and bottling.

Dandelion wine is probably the best-known example of wine made from flower parts. Although most view dandelions as a nuisance, the flower has a long history as a medicinal herb and teas. Petals are excised, boiled, and extracted in various formulations of sugar and acid (citrus fruit or juice) for several days prior to straining and addition of yeast. Since petals are typically low in available nitrogen, supplementation is required.

Berry fermentations from cultivated and native berries are relatively simple. Most have adequate to excess acidity and juice/wine yields are acceptable. Apple wine (cider, hard cider, apple jack) is also an ancient

## THE CORN GODDESS

Nearly all New World tribes had a Corn Goddess or Corn Maiden, an Earth Goddess who taught them how to grow food from her body. Often her body was sacrificed, as she demanded, so that her children could grow food on it. This became a constant reminder to her descendants to treat the land as their Mother. One of the most famous Corn Mothers was Central American Chicomeoatl, who also guarded women who had died in childbirth.

beverage, and consumption of fermented apple juice is well over two thousand years old. English colonists brought apple seeds to north America where both “hard” and nonalcoholic juice became their most popular drink. Pear wine, also known as perry or *poire*, has its origins in both the England and Normandy region of northern France. Compared with ciders, perrys have more refined and ephemeral aromas. Perry also contains a high level of the nonfermentable sugar-alcohol, sorbitol, resulting in a more full-bodied presentation.

Included in the stone fruits category are wines made from numerous varieties of peaches and nectarines, plums, apricots, and cherries. Each presents unique challenges. As noted above, the most significant issue is juice yield. Enzyme additions are helpful. Produced from either cultivated or native species, cherries yield a relatively distinctive and easily managed fruit wine. Cherry pits contain organic cyanides either as cyanogenic glycosides or hydrocyanic acid. Therefore, any cracked seeds should be separated from the pulp prior to fermentation. Among commercially available varieties, sour cherries, such as Montmorensay, are sought after due to their already high acidity. However, sweet cherries may also produce excellent wine upon blending or with acid supplementation. “Wild” or chokecherries are common to much of North America. Chokecherries derive their name from their extraordinary acidity or “sourness” compared with cultivated cherries.

**WOMEN AND FOOD.** Although the subject of women and food is of vast importance, it is difficult to document. Unfortunately for women’s history in general, early historians customarily focused on public events (usually male), and most women’s records have been discarded or lost. Further, the material we have in greatest abundance is that of the wealthy, who were literate, had large properties and kitchens to manage, and kept records. If one generalization can be made from this uneven data, it would probably be the concept that family cooking was universally associated with women and was shaped by location, period, culture, and class. Because most changes in women’s relationship to food are found in the middle status range, it will be the focus of this essay.

### Women’s Early Association with Food and Agriculture

From the earliest days of prehistory, women have not only nurtured society with their own kinds of cookery but also figured predominantly in the agricultural innovation that, to this day, feeds much of the world. Women’s place in a pervasive gender food dichotomy has defined their

power and status for millennia. In the earliest nomadic societies that subsisted on foraging and hunting, the foragers were almost always females. Men’s contribution was through the hunt. Recent archaeological findings suggest that the diet was largely vegetative (female) and was not nearly as meat-centered (male) as surviving bone remains once seemed to indicate. Nevertheless, this diet sustained extremely healthy people. The extent of women’s knowledge must have been vast, as they knew where, in their wanderings, specific plants were to be found at different times of the year and which parts of the plants were edible in different stages of their life cycle. This early gender-based pattern still exists, and survives in such nomadic cultures as the African Bushmen.

It has been suggested that the division of food responsibility was a consequence of women’s limited mobility, resulting from childbearing and extended periods of childcare. In any case, their familiarity with plants and their own identification with creating new life (the male role having been as yet unrecognized) were undoubtedly factors in their monumental innovation, the formation of the first organized agriculture (c. 8000 B.C.E.).

Evidence of the high regard women earned is reflected cross culturally in the stories of universal origin even up to and including subsequent patriarchal systems. For example, in ancient Greco-Roman mythology, the story of Demeter (Ceres), the goddess of agriculture and fertility, and her daughter Persephone (Proserpina) acknowledge women’s responsibility for developing agriculture, the origin of growing seasons, and the agrarian skills that they taught people. In distant Mexico people worshipped Ceres’ counterpart, the pre-Aztec Great Corn Mother known as Chicomeoatl; variants of her story abound in tribes and nations throughout the hemisphere.

The new agriculture did more than feed people—it changed basic human society. Food could now be produced in one place and stored there for year-round avail-

Pictures of markets the world over reveal one common theme: women selling food. In nations where agriculture is small-scale, women are usually both food producers and food retailers. The twist in this nineteenth-century woodcut is that folk costume is being exploited as a marketing ploy to call attention to the agricultural products. Woodcut from the *Neues Illustriertes Schweizer Kochbuch* [New Illustrated Swiss Cookbook] published at Zurich in 1876. ROUGHWOOD COLLECTION.

ability, and it enabled the formation of permanent settlements that preceded the growth of civilizations.

Women's agricultural revolution was followed by men's parallel development of domesticated herds and large animal husbandry, today practiced by nomadic Masai of East Africa and the shepherders of Central Asia. Their herds supplied not only food but also a reservoir of a different commodity—wealth and status.

During this time, women continued their long-established custom of cooking privately indoors to strengthen family ties and health. When men cooked, it was usually outdoors for other men, serving the religious, political, and social needs of the community. Each gender had its own kind of pots and specific areas of cuisine. Women slow-cooked moist dishes of grain and vegetable (sometimes flavored with small amounts of meat) in clay stewpots. Men tended to roast or grill meats with iron equipment. A vestige of this remains today in women's daily cooking and men's backyard barbecues. This sim-

ple division of food tasks by gender has changed very little with the centuries; the distinctive roles have blurred only as society itself has undergone major changes.

### Women in Ancient Greece and Rome

One of these changes happened with the appearance of patriarchal societies. Gender food divisions among the ancient civilizations indicate not only women cooking at home, but also some men forming a professional class of chefs that cooked for the most privileged. In Greece and Rome, for example, these chefs were noted for their elaborate presentations for upper-class banquets and epicurean occasions. At the same time, the taverns and street vendors that provided a substantial amount of food to all levels of urban society were staffed by both men and women of lower status, but with unclear gender divisions. Women of all classes were considered by men to be inferior and were restricted to "lesser" domestic duties and family service at home, but they were still credited for

## THE RIGHT TO COOK

In 1677, Beatrice Plummer found herself in the Salem, Massachusetts, courthouse. She complained that her husband had denied her not only food provisions but also the right to perform her household responsibilities by cooking properly for the household. The court fined her husband for his “abusive carriages and speeches.” The unequal division of spheres sometimes had its ironic side.—Cited in Laurel Thatcher Ulrich, *Good Wives* (1982).

their cookery. Women’s place in the middle-class kitchens sometimes became more supervisory, as slaves were easily available, but their earlier place of power and honor was gone. Under ongoing patriarchal control, such gender divisions continued to be established and enforced for centuries.

### The Middle Ages through the Early Modern Centuries

During the Middle Ages and the Renaissance, the gender divisions were increasingly reinforced by a growing system of secular and religious laws. Upper- and middle-class women remained relatively powerless at home under the rule and protection of male relatives and had no possibility of developing their own careers. There were, as always, a different set of culinary standards for male cooks, who sometimes achieved the prestigious positions denied to women. Manuscripts of their compiled recipes were written for other chefs and ultimately became the first cookbooks. Women who cooked in the urban marketplace were still working at lower-status work and may have filled a variety of positions, depending on fortune or skill. At one end of the gamut, they may have been hired as cooks in modest homes, and at the other as scullery maids. Like men, they also worked in taverns or as street vendors, perhaps as the ubiquitous and fanciful “Gingerbread Women” who sold spicy goodies at local fairs and festivals.

The rural world has always lived by its own code of gender rules. Like working-class women, farm women often participated in the workplace. In much of urban middle-class Europe, only men were permitted to function in public, where they represented their families’ interests and worked to keep the community strong. Married middle-class urban women lived more privately under the umbrella of male authority and representation. However, women commonly functioned more independently within the rural corporate family, where they traditionally contributed to family decision-making and

income. Their labors, beyond the customary cooking, kitchen gardening, preserving, caring for barnyard animals, etc., included the local sale of their own products, among them butter, eggs, cheese, fruit and vegetables, poultry, and perhaps cooked wares in season. They secured much-needed funds, as farm capital is usually tied up in buildings, stock, equipment, and cash is invariably scarce. Thus, farm women, even those of means, were early food entrepreneurs in the public market.

It should also be mentioned, in the interest of thoroughness, that women with high positions were rarely in the kitchen, apart from supervising menus or preparing occasional delicacies in honor of a special guest or occasion.

One of the few sources of material about women in this period is the world of art. Although such works are too sparse to provide a conclusive picture, they nevertheless suggest some parameters of gender roles. Many paintings from the sixteenth century show women cooking, but rarely in positions of authority. In a German print of 1507, a male chef adjusts flavorings, while a lower-status scullery maid washes (or peels) food. A Dutch image from 1510 shows important-looking men conducting business in the hall in the foreground while a woman cooks in the kitchen in the background. In eighteenth-century France, Chardin painted a series of female kitchen servants in low circumstances, depicting their fatigue and perhaps boredom. However, in the same period we see evidence of change: a Spanish painting shows two authoritative women in an elaborate Valencian kitchen, cooking and handing their platters to liveried butlers, presumably for an important feast. Likewise, the frontispiece of Eliza Smith’s cookbook (London, 1727) shows in the foreground three women in charge of the kitchen, while in the background one sees the suggestion of a butler carrying a tray into the dining room beyond. This is consistent with an event in the American colony of Virginia, in which the English Governor Bottetourt hired a woman (unnamed in the records) to replace his retiring steward William Marshman. Over a century later, Isak Dinesen’s short story “Babette’s Feast” centered on a French female chef who embodied Dinesen’s youthful professional dreams, perhaps indicating that such careers for women were becoming more conceivable. These isolated examples in themselves give suggestions of possible circumstances but obviously wield more clout when combined with sources such as cookbooks.

### Women and Cookbooks

The printing press and other incipient technologies made a new genre of cookbooks possible, this time for a widening audience of middle-class urban women. They had begun to work with this audience by the late 1500s. In a field dominated by men, the first published works, under male *noms de plume*, guided affluent and literate women who presided over privileged estates and well-appointed home kitchens. Cookbook writing was essentially done

in private; anonymity hid its entrepreneurial aspect and circumvented the social code. More often, male writers, such as Gervase Markham (*The English Housewife*, 1615) and Richard Bradley (*The Country Housewife and Lady's Director*, 1732), writing for this female audience used recipes from women's manuscripts without noting their sources.

By the eighteenth century, middle-class women driven by economic need began publishing cookbooks for other women under their own names. They often incorporated the knowledge and experience of their own kitchens with more complex hospitality food. In a few cases they were the work of the more privileged, who wrote as a social service. These cookbooks appeared in differing numbers throughout European cultures: England's strong middle class produced many, while France, with a different social and economic system, produced relatively few. Women of other established traditions, among them German, Polish, Dutch, Spanish, and Scandinavian, were also represented.

Many of these early cookbooks were carried around the world by emigrating colonists. For example, Eliza Smith's *The Compleat Housewife* (London, 1727) and Hannah Glasse's *Art of Cookery* (London, 1747) were used extensively in North American settlements. Amelia Simmons, author of *American Cookery*, the first American cookbook (1796), followed their lead with her commonly used English-American cuisine. Those who followed her were, interestingly enough, women of stature who were justly famous for their works on women's affairs and social and political reform. These culinary pioneers of the new American democracy presented a new public female image of independence, competence, and enterprise. By the mid-nineteenth century, growing literacy and lowering book prices made cooking manuals available in increasing numbers and by the century's end, they were owned in large numbers throughout the nation. Noted authors such as Marion Harland, Maria Parloa, Sarah Tyson Rorer, and Fannie Farmer also ran cooking schools, wrote newspaper and magazine columns, and lent their names and reputations to new product endorsements and advertisements. Their influence helped to mold a unified national American cuisine, and sometimes they used their culinary forum to support women's social or religious issues.

The changing nature and proliferation of women's cookbooks unwittingly documented a shift in women's general social and economic position. Many cookbooks were prefaced with dedications to brides and young matrons of the urban middle class, with the comment that young women were no longer learning housekeeping at home and were unprepared to run their own homes. The early years that girls had traditionally spent learning these tasks were now dedicated to education in public school, perhaps followed by finishing school or college, and then by jobs that lasted until marriage. Women were nevertheless expected to acquire domestic skills and to aspire

## ACTIVIST COOKS

Capable women who wrote cookbooks were often noted for their other public activities. Lydia Maria Child, author of *The Frugal Housewife* (1832) also wrote widely on social and political issues; Sarah Josepha Hale (1849) edited Godey's *Lady's Book*—the preeminent women's periodical of the time; and Catharine Beecher, who published *Domestic Receipt* in 1846, also campaigned widely for strong women's professions in education and the home.

to the idealized Victorian separation of gender responsibilities, the "Doctrine of Separate Spheres," under which women avoided involvement in the public world of work. One of their sanctioned spheres, that of service to the community, revealed indications of the changes to come.

### Women in the Public Sphere

The growing female philanthropic movement used home-cooking skills to produce fund-raising cookbooks, church suppers, food festivals, and bake sales. Women's Exchanges supported middle-class women in straitened circumstances by selling their home-cooked foods, often in special lunchrooms. These educational and charitable activities taught basic business skills, which had hitherto been held only by men. By the early 1920s, their example (and the new automobile) inspired female tearooms and luncheonettes, run by and geared to women, and serving a feminine "dainty" cuisine. It is entirely likely that this major step in women's progress toward economic equality succeeded because it utilized the familiar, accepted, and integral bonds between women, food, and community service.

Cookbook writing was only one activity related to the growth of cities in the early nineteenth century. Yeoman farm women had spent much of their time in food work, but once transplanted to the city they found alternative opportunities in the emerging middle class, the cash economy, and entrepreneurship. For example, Pearl Rivers (whose real name was Elizabeth Jane Poitevent Nicholson), the first woman publisher of a major newspaper (*The Picayune*, New Orleans), used her position to organize field research, collect local home-based recipes, and preserve the disappearing but cherished Creole cuisine in *The Picayune Creole Cookbook*, 1900.

The amalgam of cultures in the United States allowed for differing women's roles. New England's separate spheres doctrine, promoted in women's writings nationally, kept middle-class urban women out of the

marketplace, while New Orleans's internationally based culture encouraged them. For example, Madame Begue, an accomplished Bavarian chef relocated in New Orleans, earned an impressive reputation with her Creole food as both restaurateur and cookbook author (1900). She was, in many ways, like the skillful French matriarchs drawing on their own home cooking and running bistros. Some women ran boardinghouses and competed on the merits of their kitchens. They are credited with molding a generation of young farm men relocating in growing cities, and in many ways directing the course of the emerging middle class. Other work opportunities opened in higher education with the establishment of federally mandated land grant colleges (1862) and the developing schools of home economics at which food study was elevated to a more academic level. They trained middle class women for significant food careers in nutrition, social work, and education.

### The Late Twentieth Century

The Great Depression, the World Wars, and the post-war return to normalcy did relatively little to change basic American cuisine or women's home responsibility for it. However, in the 1970s the women's movement began to weaken traditional gender divisions, and women at home were exposed to a new wave of highly visible professional female cooks and authors. Julia Child and Alice Waters familiarized homemakers with innovative food, and incidentally offered a model of the professional female. Inspired by such luminaries, a succession of TV cooking shows, and the growing feminist emphasis on business careers, numbers of capable young women began to operate their own restaurants, bakeries, and publications. Female journalists such as Mimi Sheraton, Gael Greene, and Ruth Reichl found a niche as food essayists, critics, and restaurant reviewers. In academia food became a more acceptable subject for professional attention as the social sciences began the study of women as food-givers through the perspectives of history, sociology, anthropology, archaeology, and folklore.

### The Twenty-first Century

While a good part of the undeveloped and developing world still identifies women with traditional home cooking, the food role of women in developed nations is in a period of change, a logical response to shifting economic opportunities and family structure. As women increasingly work away from home, they have, of necessity, reduced their customary domestic food preparations. Many men have accepted some of the responsibility for daily cooking (a new role for them), perhaps continuing to cook a special (often gourmet) menu for weekend guests.

As traditional domesticity becomes more scarce, Martha Stewart's style of home cookery has vindicated the ancient female role for those at home, assuring her female audience of renewed status and satisfaction. Many women know far less about cookery than their mothers did and have asserted their perceived liberation from

household drudgery with the proud statement, "I don't cook." Fortunately or not, their daughters often lack basic skills and culinary understanding. Having experienced neither instruction nor the memory of food cooked from natural ingredients, they tend to associate good dining with the elusive processes of restaurants. As women establish a respected place in the professional work force and prepare the food that had been associated with men since antiquity, the old dichotomy of men's food and women's food has begun to slip. At the same time, fast food, convenience, and "take-out" foods, which are, in a sense, the traditional male cuisine, are replacing the comfort foods associated with women's home cooking. It would seem that economic progress has weakened associations between gender and cuisine and the link between women and food, leaving us to ponder the consequences.

**ZOROASTRIANISM.** The prophet Zarathushtra (known to the Greeks as Zoroaster) founded Zoroastrianism, one of the world's oldest living religions, in north-eastern Iran, probably between 1800 to 1000 B.C.E. Zoroastrianism became the state religion of the first Persian Empire in the sixth century B.C.E. after which its influence waxed and waned until finally it was supplanted by Islam in the seventh century C.E. In the tenth century B.C.E. a small group of Zoroastrians migrated to the Gujurat region of northwest India where they became known as Parsis (Persians). Today, the number of adherents is estimated at 274,000 worldwide with the largest community centered around Bombay and a smaller number in the Iranian homeland. Zoroastrians follow the creed of "good thoughts, good words, good deeds" and uphold virtues of honesty, charity and hospitality.

### Role of Food in Zoroastrian Tradition

Dietary laws and food proscriptions are not part of original Zoroastrian teachings. Nevertheless certain ritual and symbolic uses of food have evolved over time, based on later Zoroastrian writings and as a consequence of interaction with other cultures and religions. For example, Zoroaster abolished the tribal custom of animal sacrifice, though it quickly reemerged and became incorporated in Zoroastrian rituals. Today it survives only amongst Iranian Zoroastrians during the festival of Mehregan, when meat and bread are distributed. Generally all foods are permitted and are consumed according to personal preference and local custom. For example, Zoroastrians often forgo pork and beef in deference to their Hindu and Moslem neighbors, or are vegetarian by choice. Certain foods may still be avoided because they belong to the evil counter creation. These include birds of prey and "hideous fish." Carrion is regarded as impure as is any food coming into contact with it.

The concept of purity versus impurity is central to Zoroastrianism. Cleanliness is highly regarded and purification rites are a part of most ceremonies. Formerly there were elaborate codes to preserve food from impurities such as skin, nail clippings, sweat, blood, and excreta. It was forbidden to eat or drink from a common cup, and priests would not accept food from non-Zoroastrians. Although cleanliness and purity remain as important values, ritual practices have declined amongst ordinary Zoroastrians. Constraints of contemporary urban life, and differing interpretations by orthodox and reform groups within the faith also contribute to variations in actual practice. It is also notable that fasting—a common religious discipline—plays no part in the faith. Asceticism and renunciation, of which fasting is an integral part, are forbidden.

### Symbolism and Sacred Foods

Rituals are important in Zoroastrianism. They establish a connection between the material and spiritual universes. Food plays a part in rituals, as a thanksgiving to God and

Ruins of ancient Persian fire altars at Naqch-E-Rostem, Iran. © CHARLES AND JOSETTE LENARS/CORBIS.

as a symbol of fellowship created through sharing of material bounty. There are certain foods that are symbolic of the various creations of Ahura Mazda and are therefore regarded as being superior and thus suitable for use in religious rituals and ceremonies. These include bread (*dron*), milk, water, ghee, rice, dates, and pomegranates. *Dron* is an unleavened bread made from wheat flour and ghee. It may be prepared only by a member of a priestly family. During the preparation of the bread the words *humata*, *bukhta*, *hvarshta* (good thoughts, good words, good deeds) are intoned three times, accompanied by placing a mark on the bread, for a total of nine marks. This bread of life is a source of spiritual strength. Haoma (*hom*) juice extracted from the haoma plant is used in a number of rituals. It contains a mild narcotic.

The pomegranate, being an evergreen, is a symbol of everlasting life and of the fecundity of nature. It is also a symbol of prosperity and plenty because of its numerous seeds. Pomegranate leaves are chewed during purification rituals at initiation ceremonies, marriages, after childbirth and by those who have come into contact with corpses. (There has been a modern decline in the latter practice). Rice, as in the Hindu tradition, represents happiness and prosperity.

### Ceremonies and Ritual

Yasna is the most important of the Zoroastrian ceremonies. It is celebrated daily, but only in Iranian and Indian fire temples and only by qualified priests. Yasna is an "inner" ceremony, which only Zoroastrians may attend and is often specially commissioned by community members. Ritual materials used include haoma with pomegranate twigs, goat's milk, *dron* with ghee, water, and a presanctified mixture known as *parahom*. The water signifies health and wellbeing, while the milk represents the presence of Vohu Manah, the protector of the animal kingdom. The haoma twigs and pomegranate leaves are pounded with consecrated water and milk is

TABLE 1

Zoroastrian festivals				
Name	Season	Description	Creation link	Dates
Maidh-yo-zarem	mid-spring	Fresh vegetables in plenty	Sky	April 30–May 4
Maidh-yo-shema	mid-summer	Time for harvesting corn	Water	June 29–July 3
Paiti-Shahem	early autumn	Harvesting of fruit	Earth	September 12–16
Aya-threm	mid-autumn	Sowing of winter crops	Plants	October 13–17
Maidh-yar-em	mid-winter	Period of perfect rest	Cattle	January 1–5
Hamas-path-maedern	pre-spring	Equality of heat and cold	Man	March 16–20
Nou Rouz	spring	Renewal of life	Fire	March 21

The Zoroastrian year is based on a solar calendar and starts at the exact time of the vernal equinox.

SOURCE: Adapted from the website of the Ancient Iranian Cultural and Religious Research and Development Centre ([www.ancientiran.com](http://www.ancientiran.com)).

added to the mixture, some of which is then poured out into a well from whence it will flow out to strengthen the whole of creation. The remainder of the mixture is offered first to those present who endowed the ceremony and then to other observers.

One of the main Zoroastrian “outer” ceremonies, Afrinagan, may be performed in any suitable clean place and can be witnessed by Zoroastrians and non-Zoroastrians alike. Its purpose is to praise the bounty of Ahura Mazda and to request His blessings on members of the community. Ritual objects include a tray of food, usually fruit, wine, eggs, milk and water, which serves as a visible sign of Ahura Mazda’s generosity and care for the wellbeing of his people. The main feature of the ritual is a threefold exchange of flowers between the officiating priests.

After giving birth, a woman should be confined with her baby for a period of forty days in order to allow the impurities she has contacted to dissipate. For modern urban Zoroastrian women this requirement not to leave the house for nearly six weeks is extremely difficult to fulfill. As a compromise the woman eats separately from the rest of the family. After forty days she takes a ritual bath that allows her to rejoin the wider community. The new baby may be given a drop of consecrated *hom* from a Yasna ceremony as a “strengthening drink.” If this is not possible a drink may be made from *hom* twigs, pomegranate leaves and water.

Children are initiated into the Zoroastrian faith at age seven to eleven years (Parsi) or twelve to fifteen years (Iranian), at which time they become responsible for fully observing Zoroastrian practices. At the initiation ceremony (Naojote) the child receives a sacred white shirt (*sudra*) and a sacred cord (*kushti*). A ceremonial tray prepared for the ceremony contains a mix of rice, pomegranate, raisins, almonds, and slices of coconut. The officiating priest who blesses the child pours these over the head of the child. A banquet for family and friends follows the initiation ceremony.

Marriage ceremonies take place at the house of the bride or in public places where large crowds can congregate. Prior to the actual marriage ceremony the bridegroom, with family friends and priests, arrives at the bride’s house. While the others enter the house the groom remains on the threshold where he is greeted with traditional symbols of welcome. An egg, a coconut, and a dish of water are successively passed around his head, then dashed to the floor. The groom may then enter the house and the marriage ceremony commences. During the ceremony the priest sprinkles rice on the bride and groom who also sprinkle each other with rice. A feast for family and friends follows the marriage ceremony.

After a death, consecrated food, such as *dron* or eggs is offered to sustain the soul of the newly departed. The family of the deceased may not eat meat for three days, a practice that may be linked to fear over impurities or to the idea that flesh food is more suitable for celebratory occasions. On the anniversary of a death the souls of the departed are offered cooked foods, milk, water, and fresh fruit. This food is subsequently given to charity. These observances, like others, may be in decline.

### Holidays and Festivals

Zoroaster established a series of holy days and also assimilated existing traditional festivals and celebrations. There are six seasonal festivals known as Gahambars, which celebrate the six creations of Sky, Water, Earth, Plants, Cattle, and Man. Traditionally each lasted for five days, though now much curtailed, and included feasting, prayer and rejoicing. The most important festival is that of Nou Rouz—the New Year. Held at the spring equinox it celebrates the rejuvenation of nature and the beginning of new life, and is linked to fire—the seventh and most sacred creation of Ahura Mazda. It is marked by family and community gatherings, religious services, feasting, and gift giving. The ten days prior to Nou Ruz are for commemoration of the departed. A variety of grains and lentils are soaked so that they will germinate in time for the holiday. These green sprouts are added to a thanksgiving table that also holds a variety of other symbolic objects and foods such as bread, fruit, fresh vegetables, sugar cones, and decorated eggs.

Each day in the Zoroastrian calendar is dedicated to a particular divine being or important event, twelve of

which also has its own month. Name-day feasts are held when month name and day name coincide. Adar, the ninth day of the ninth month, is celebrated as the birthday of fire and is a time to give thanks for warmth and light. Traditionally food is not cooked in the home, to give the fire a rest. Other festivals include the birth and death anniversary of the prophet and the feast of all souls (Muktdad) for remembrance of departed family members.

## APPENDIX: DIETARY REFERENCE INTAKES

---

The table on the pages that follow lists vitamins, their food sources, and adverse effects of over-consumption. The table gives recommended intake (RDA) and—a feature not available in previous RDA lists—shows tolerable upper levels that readers can use as a guideline to prevent excess consumption.

The reference values are referred to collectively as the Dietary Reference Intakes (DRIs) and include Recommended Dietary Allowance (RDA), Adequate Intake (AI), and the Tolerable Upper Intake Level (UL). A requirement, which can vary depending on age, gender, and life stage, is defined as the lowest continuing intake level of a nutrient that will maintain a defined level of nutrition in an individual. (The nutrient levels published in the DRI reports apply to the healthy general population. They are not expected to be sufficient for individuals who are already malnourished, nor would they be adequate for disease states known to have increased nutrient requirements.)

The table was developed by the Institute of Medicine's Standing Committee on the Scientific Evaluation of Dietary Reference Intakes, in cooperation with Health Canada. In 1995 the Food and Nutrition Board of the Institute of Medicine—part of the National Academy of Sciences—appointed the committee to replace the tenth (1989) edition of the Recommended Dietary Allowances (RDAs) document.

## Dietary reference intakes: Vitamins

Nutrient	Function	Life stage group	RDA/AI*	UL <sup>a</sup>	Selected food sources	Adverse effects of excessive consumption	Special considerations
Biotin	Coenzyme in synthesis of fat, glycogen, and amino acids	Infants	(µg/d)		Liver and smaller amounts in fruits and meats	No adverse effects of biotin in humans or animals were found. This does not mean that there is no potential for adverse effects resulting from high intakes. Because data on the adverse effects of biotin are limited, caution may be warranted.	None
		0–6 mo	5*	ND <sup>b</sup>			
		7–12 mo	6*	ND			
		Children					
		1–3 y	8*	ND

## Dietary reference intakes: Vitamins

Nutrient	Function	Life stage group	RDA/AI*	UL <sup>a</sup>	Selected food sources	Adverse effects of excessive consumption	Special considerations
<b>Folate</b>  Also known as: Folic acid Folacin Pteroylpolyglutamates  Note: Given as a dietary folate equivalents (DFE). 1 DFE = 1 µg food folate = 0.6 µg of folate from fortified food or as a supplement consumed with food = 0.5 µg of a supplement taken on an empty stomach.	Coenzyme in the metabolism of nucleic and amino acids; prevents megaloblastic anemia	Infants	(µg/d)	(µg/d)	Enriched cereal grains, dark leafy vegetables, enriched and whole-grain breads and bread products, fortified ready-to-eat cereals	Masks neurological complication in people with vitamin B <sub>12</sub> deficiency.  No adverse effects associated with folate from food or supplements have been reported. This does not mean that there is no potential for adverse effects resulting from high intakes. Because data on the adverse effects of folate are limited, caution may be warranted.  The UL for folate applies to synthetic forms obtained from supplements and/or fortified foods.	In view of evidence linking folate intake with neural tube defects in the fetus, it is recommended that all women capable of becoming pregnant consume 400 µg from supplements or fortified foods in addition to intake of food folate from a varied diet.  It is assumed that women will continue consuming 400 µg from supplements of fortified food until their pregnancy is confirmed and they enter prenatal care, which ordinarily occurs after the end of the periconceptional period—the critical time for formation of the neural tube.
		0–6 mo	65*	ND <sup>b</sup>			
		7–12 mo	80*	ND			
		Children					
		1–3 y	150	300			
		4–8 y	200	400			
		Males					
		9–13 y	300	600			
		14–18 y	400	800

## Dietary reference intakes: Vitamins

Nutrient	Function	Life stage group	RDA/AI*	UL <sup>a</sup>	Selected food sources	Adverse effects of excessive consumption	Special considerations
Thiamin	Coenzyme in the metabolism of carbohydrates and branched-chain amino acids	Infants	(mg/d)		Enriched, fortified, or whole-grain products; bread and bread products, mixed foods whose main ingredient is grain, and ready-to-eat cereals	No adverse effects associated with thiamin from food or supplements have been reported. This does not mean that there is no potential for adverse effects resulting from high intakes. Because data on the adverse effects of thiamin acid are limited, caution may be warranted.	Person, who may have increased needs for thiamin include those being treated with hemodialysis or peritoneal dialysis, or individuals with malabsorption syndrome.
Also known as: Vitamin B1 Aneurin		0–6 mo	0.2*	ND <sup>b</sup>

## Dietary reference intakes: Vitamins

Nutrient	Function	Life stage group	RDA/AI*	UL*	Selected food sources	Adverse effects of excessive consumption	Special considerations
Vitamin B <sub>6</sub> Vitamin B <sub>6</sub> comprises a group of six related compounds: pyridoxal, pyridoxine, pyridoxamine, and 5'-phosphates (PLP, PNP, PMP)	Coenzyme in the metabolism of amino acids, glycogen and sphingoid bases	Infants	(mg/d)	(mg/d)	Fortified cereals, organ meats, fortified soy-based meat substitutes	No adverse effects associated with Vitamin B <sub>6</sub> from food have been reported. This does not mean that there is no potential for adverse effects resulting from high intakes. Because data on the adverse effects of Vitamin B <sub>6</sub> are limited, caution may be warranted.  Sensory neuropathy has occurred from high intakes of supplemental forms.	None
		0–6 mo	0.1*	ND <sup>b</sup>			
		7–12 mo	0.3*	ND			
		Children					
		1–3 y	<b>0.5</b>	30

		31–50 y	<b>2.0</b>	100			
Vitamin B <sub>12</sub> Also known as: Cobalamin	Coenzyme in nucleic acid metabolism; prevents megaloblastic anemia	Infants	(μg/d)	(μg/d)	Fortified cereals, meat, fish, poultry	No adverse effects have been associated with the consumption of the amounts of Vitamin B <sub>12</sub> normally found in foods or supplements. This does not mean that there is no potential for adverse effects resulting from high intakes. Because data on the adverse effects of vitamin B <sub>12</sub> are limited, caution may be warranted.	Because 10 to 30 percent of older people may malabsorb foodbound vitamin B <sub>12</sub> , it is advisable for those older than 50 years to meet their RDA mainly by consuming foods fortified with vitamin B <sub>12</sub> or a supplement containing vitamin B <sub>12</sub> .

## Dietary reference intakes: Vitamins

Nutrient	Function	Life stage group	RDA/AI*	UL*	Selected food sources	Adverse effects of excessive consumption	Special considerations
Vitamin E	A metabolic function has not yet been identified. Vitamin E's major function appears to be as a non-specific chain-breaking antioxidant.	Infants 0–6 mo 7–12 mo  Children 1–3 y 4–8 y  Males 9–13 y 14–18 y 19–30 y 31–50 y 50–70 y > 70 y  Females 9–13 y 14–18 y 19–30 y 31–50 y 50–70 y > 70 y  Pregnancy ≤ 18 y 19–30 y 31–50 y  Lactation ≤ 18 y 19–30 y 31–50 y	(mg/d) 4* 5*  6 7  11 15 15 15 15 15  11 15 15 15 15 15  15 15 15  19 19 19	(mg/d) ND <sup>b</sup> ND  200 300  600 800 1,000 1,000 1,000 1,000  600 800 1,000 1,000 1,000 1,000  800 1,000 1,000  800 1,000 1,000	Vegetable oils, unprocessed cereal grains, nuts, fruits, vegetables, meats	There is no evidence of adverse effects from the consumption of vitamin E naturally occurring in foods.  Adverse effects from vitamin E containing supplements may include hemorrhagic toxicity.  The UL for vitamin E applies to any form of α-tocopherol obtained from supplements, fortified foods, or a combination of the two.	Patients on anti-coagulant therapy should be monitored when taking vitamin E supplements.
Also known as: α-tocopherol							
Note: As α-tocopherol. α-Tocopherol includes <i>RRR</i> -α-tocopherol, the only form of α-tocopherol that occurs naturally in foods, and the <i>2R</i> -stereoisomeric forms of α-tocopherol ( <i>RRR</i> -, <i>RSR</i> -, <i>RRS</i> -, and <i>RSS</i> -α-tocopherol) that occur in fortified foods and supplements. It does not include the <i>2S</i> -stereoisomeric forms of α-tocopherol ( <i>SRR</i> -, <i>SSR</i> -, <i>SRS</i> -, and <i>SSS</i> -α-tocopherol), also found in fortified foods and supplements.							
Vitamin K	Coenzyme during the synthesis of many proteins involved in blood clotting and bone metabolism	Infants 0–6 mo 7–12 mo  Children 1–3 y 4–8 y  Males 9–13 y 14–18 y 19–30 y 31–50 y 50–70 y > 70 y  Females 9–13 y 14–18 y 19–30 y 31–50 y 50–70 y > 70 y  Pregnancy ≤ 18 y 19–30 y 31–50 y  Lactation ≤ 18 y 19–30 y 31–50 y	(μg/d) 2.0* 2.5*  30* 55*  60* 75* 120* 120* 120* 120*  60* 75* 90* 90* 90* 90*  75* 90* 90*  75* 90* 90*	(μg/d) ND ND  ND ND  ND ND ND ND ND ND  ND ND ND ND ND ND  ND ND ND  ND ND ND	Green vegetables (collards, spinach, salad greens, broccoli), brussel sprouts, cabbage, plant oils and margarine	No adverse effects associated with vitamin K consumption from food or supplements have been reported in humans or animals. This does not mean that there is no potential for adverse effects resulting from high intakes. Because data on the adverse effects of vitamin K are limited, caution may be warranted.	Patients on anti-coagulant therapy should monitor their vitamin K intake.

[continued]

## Dietary reference intakes: Vitamins

Note: The table is adapted from the DRI reports, see [www.nap.edu](http://www.nap.edu). It represents Recommended Dietary Allowances (RDAs) in **bold type**, Adequate Intakes (AIs) in ordinary type followed by an asterisk (\*), and Tolerable Upper Intake Levels (ULs)<sup>a</sup>. RDAs and AIs may both be used as goals for individual intake. RDAs are set to meet the needs of almost all (97 to 98 percent) individuals in a group. For healthy breastfed infants, the AI is the mean intake. The AI for other life stage and gender groups is believed to cover the needs of all individuals in the group, but lack of data prevent being able to specify with confidence the percentage of individuals covered by this intake.

<sup>a</sup>UL = The maximum level of daily nutrient intake that is likely to pose no risk of adverse effects. Unless otherwise specified, the UL represents total intake from food, water, and supplements. Due to lack of suitable data, ULs could not be established for vitamin K, thiamin, riboflavin, vitamin B<sub>12</sub>, pantothenic acid, biotin, or carotenoids. In the absence of ULs, extra caution may be warranted in consuming levels above recommended intakes.

<sup>b</sup>ND = Not determinable due to lack of data of adverse effects in this age group and concern with regard to lack of ability to handle excess amounts. Source of intake should be from food only to prevent high levels of intake.

SOURCE: *Dietary Reference Intakes for Calcium, Phosphorous, Magnesium, Vitamin D, and Fluoride* (1997); *Dietary Reference Intakes for Thiamin, Riboflavin, Niacin, Vitamin B<sub>6</sub>, Folate, Vitamin B<sub>12</sub>, Pantothenic Acid, Biotin, and Choline* (1998); *Dietary Reference Intakes for Vitamin C, Vitamin E, Selenium, and Carotenoids* (2000); and *Dietary Reference Intakes for Vitamin A, Vitamin K, Arsenic, Boron, Chromium, Copper, Iodine, Iron, Manganese, Molybdenum, Nickel, Silicon, Vanadium, and Zinc* (2001). These reports may be accessed via [www.nap.edu](http://www.nap.edu).

# SYSTEMATIC OUTLINE OF CONTENTS

---

This systematic outline provides a general overview of the conceptual scheme of the *Encyclopedia*, listing the titles of each entry and subentry. The outline is divided into twenty-seven parts.

- 1 Foods: Staple Foods
- 2 Foods: Cooked, Processed, and Prepared
- 3 Icon Foods and Superfoods
- 4 Beverages
- 5 Food Production
- 6 Food Storage
- 7 Food Distribution
- 8 Food Preparation, Processing, and Disposal
- 9 Food Consumption
- 10 The Premodern World
- 11 Regions, Cultures, Groups
- 12 Human Evolution
- 13 Nutrition, Health, and Food Sciences
- 14 Biological Basis of Nutrition and Digestion
- 15 Psychology of Eating
- 16 Diet
- 17 Constituents of Food
- 18 Conditions, Disorders, and Diseases
- 19 Hunger
- 20 Policy
- 21 Food and Society
- 22 Religion
- 23 Feasts, Festivals, and Fasts
- 24 Food as Symbol and Commodity
- 25 Writing about Food
- 26 Study of Food
- 27 Biographies

Because the section headings are not mutually exclusive, certain entries in the *Encyclopedia* are listed in more than one section.

## FOODS: STAPLE FOODS

Apple  
Arthropods: Insects, Arachnids, and Crustaceans  
Banana and Plantain

**France** Detail of a painting by Charles Giraud called *La Salle à manger de la Princesse Mathilde* (1854), showing the interior of a grand salon fitted out with carpets, plants, and a sumptuous dinner service under silver covers. Courtesy of the Musée national du Château Compiègne, France. ©Réunion des Musées Nationaux/Art Resource, New York.

---

**Nuts** Cashew nuts in the market of Guatemala City, Guatemala. © Dave G. Houser/CORBIS.

---

---

**Top left: Onions and Other Alliums** A Welsh bunching onion in the Roughwood Seed Collection. Photo by L. Wilbur Zimmerman.

**Top right: Onions and Other Alliums** The earliest color depiction of the poor man's leek or Welsh bunching onion. From *Curtis's Botanical Magazine* (London, 1809). Some of the most accurate depictions of heirloom vegetables can be found in this annual, which is still published today. Roughwood Collection.

**Below: Onions and Other Alliums** Shallots poached in Madeira. Food styling by William Woy Weaver. Photo by André Baranowski.

---

**Top: Pastry** Marzipan mold depicting fruits and nuts. South German, circa 1750. Collection of Charles Thomas.

**Below: Pastry** A selection of Tuscan pastries. Photo by André Baranowski.

**Russia** *Merchant's Wife at Tea* (1918) by Russian painter Boris Kustodiev. In this portrait of contented overabundance, Kustodiev depicts all of the symbols of Russian culture. Courtesy of The Russian Museum, St. Petersburg.

***Inset:* Russia** Caviar has been considered a luxury food since Byzantine times, although the eggs of several different species of fish have been employed in making it. The black Beluga caviar from sturgeon is the most highly prized by connoisseurs. It is served here Polish style with new potatoes and sour cream. Photo by André Baranowski.

---

**Bottom: South America** Market scene in Sucre (formerly Chuquisaca), Bolivia. Photo by R. E. Salazar.

**Top right: Tomato** Still life with tomato by Philadelphia painter Raphaëlle Peale, circa 1795. This work is noteworthy not only because Peale's painting is one of the earliest depictions of the tomato in American art, but the tomato itself is a rare variety from the Amazon basin. Courtesy of Wadsworth Atheneum, Hartford, Connecticut. The Ella Gallup Sumner and Mary Catlin Sumner Collection Fund.

**Top left: Tomato** Detail of the so-called "Reisetomate" from the former botanical collection of the Duke of Braunschweig. This tomato, depicted in the Peale still life, was collected in Brazil during a botanical expedition in 1836. The Roughwood Seed Collection. Photo by Rob Cardillo.

**United States/Pennsylvania Dutch Food** Duck Pond at Ronks, Lancaster County, Pennsylvania. A typical Old Order Mennonite farmstead in the heartland of the Pennsylvania Dutch region. Photo by William Woys Weaver.

**Top left: Utensils** The “Colonial Breakfast Skillet” made by the Griswold iron foundry in Erie, Pennsylvania, circa 1910. In this skillet the Victorian idealization of an entire colonial meal was condensed into an iron serving utensil that foreshadowed the TV dinner. Roughwood Collection.

**Bottom: Utensils** Earthenware food vessels from ancient China. From left to right: late Anyang period *jue*, eleventh century B.C.E.; Han Dynasty jar with textile impressions, 206 B.C.E.–220 C.E.; Eastern Han Dynasty spoon, 25–220 C.E.; Machang phase of Majiayao culture jar with snakes, late third millennium B.C.E.; Western Han Dynasty two-handed jar, second century B.C.E.; Western Han Dynasty *ding*, 206 B.C.E.–24 C.E. © Royal Ontario Museum/CORBIS.

**Top right: Wheat** Cypriot family making *trachanás*, cracked wheat cooked in goat’s milk, then dried in the sun for use in soups during the winter. Photo by Charalambos Christodoulou.

**Wine** Rows of bottles of vintage wine in storage, like books on the shelves of an ancient library, or rows of crops ripening before harvest, symbolize both the cultivation and the eventual enjoyment of the fruits of labor. © Charles O'Rear/CORBIS.

# INDEX

Bold page numbers (e.g., **3:437–439**) refer to the main entry on the subject. Page numbers in italics refer to illustrations, figures, and tables. Page numbers followed by the abbreviation *tab* indicate a table within the article. The abbreviation *col. ins.* refers to the color inserts in each volume. (The color inserts are arranged in alphabetical order.)

References to contributors of articles in this encyclopedia may appear in the index, but the best way to find a writer's article(s) is to look in the Directory of Contributors that begins on page 589; articles are listed under the person's name.
